

Results on QCD jet production at the LHC (incl. Heavy flavours)

R. Seuster (TRIUMF)

On behalf of the ATLAS and CMS collaborations

Recontres du Vietnam
August 11th – 17th, 2013
“Windows on the Universe”

Outline

- Introduction
- Jet Reconstruction and Calibration
- Jet Cross Sections
- Determination of α_s
- Colour Coherence
- Heavy Flavours
- Summary and Conclusions

Introduction - QCD

- LHC is a discovery machine (→ Higgs 1st anniversary)
- Why doing QCD measurements ?
 - dominant process at LHC
 - LHC provides previously inaccessible energy regime
 - provides wealth of new measurements
 - constrain PDFs – parton density functions
 - last but not least: main background for many searches
- Why measuring (QCD) Jets ?
 - manifest confinement i.e. no free quarks
 - reflect approximately interactions of partons

Introduction - LHC

- excellent performance of LHC over last years
 - huge datasets to analyse
 - ATLAS 2012: $\sim 21 \text{ fb}^{-1}$
 - 2011: $\sim 5 \text{ fb}^{-1}$
 - 2010: $\sim 50 \text{ pb}^{-1}$
- varying levels of pileup during run 1, from \sim zero up to almost 40 coll./xing!
 - in active development
 - some QCD measurements done with low pileup data from (mostly) 2011
 - some even from 2010

Jet Reconstruction + calibration

Jet Algorithm: iterative procedure to cluster particles to new pseudo particles based on a measure of distance until a cut-off R is reached
 now anti- k_T recombination scheme commonly used

both ATLAS and CMS have non-compensating calorimeters for hadrons
 requires dedicated jet energy calibration (JES)

Jet Reconstruction and Calibration

- Jets reconstructed from electromagnetic clusters of calorimeter cells using **Anti- k_T algorithm with $R = 0.4$ and $R = 0.6$**
- Jet Energy Scale calibration applied:

- Jet Energy Scale (JES) dominant experimental uncertainty

Uncertainties derived from single hadron response and Monte Carlo simulation

Uncertainties confirmed using insitu response measurements

Jet Reconstruction & Energy Scale Calibration

- Anti- k_T clustering algorithm** : Infrared and collinear safe. Used with $R=0.5$ and 0.7 .
- Particle Flow Jets (PF Jets)** : The CMS global event reconstruction (PF) is an event reconstruction technique which reconstructs and identifies all stable particles in the event, through the optimal combination of all CMS sub-detectors. PF Jets are the output of anti- k_T on the reconstructed particles.

- For the Jet energy scale calibration CMS adopted a Factorized approach.

$$\text{Calibrated Jet} = \text{Raw Jet} \times \text{Offset Correction (pile-up)} \times \text{Relative Correction (vs } \eta) \times \text{Absolute Correction (vs } p_T)$$

CMS :
 JME-10-003
 JME-10-010
 JINST 6 2011
 DP2012-006

See also EPS talk:
 "Jet performance in CMS" by
 H. Kirschenmann

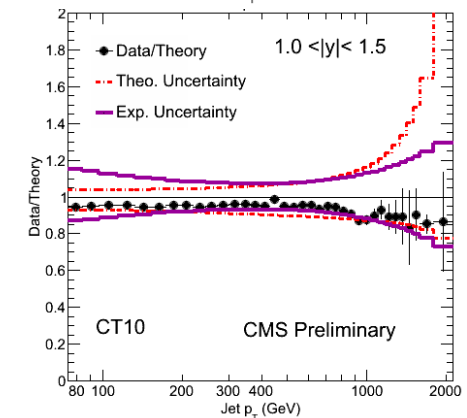

Jet p_T resolution:
 $\approx 9\%$ at 100 GeV

for 2012 new calibration and new pileup subtraction schemes are being developed

Inclusive Jet Cross Section at 8 TeV

CMS SMP-12-012

JES dominating experimental systematic uncertainty

→ good agreement over several orders of magnitude !
 differences data – MC mostly smaller than systematic uncertainties
 NLO PDF sets agree well with data (except ABM11 – not shown here)

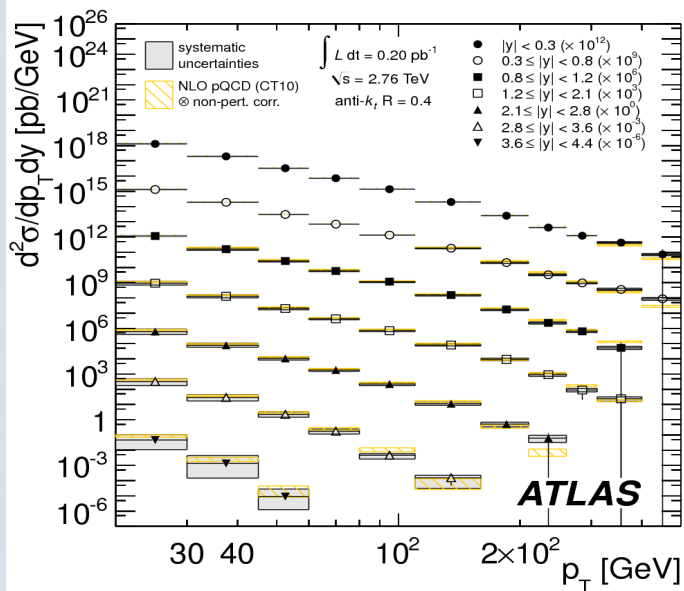

Ratio of Jet Cross Sections at 2.76 TeV and 7 TeV

ATLAS arXiv: 1304.4739

correlations reduce systematic uncertainties such that PDF can be constrained
 $\sqrt{s}=2.76\text{TeV}$, $L=0.20\text{pb}^{-1}$, anti- k_T with $R=0.4$ and $R=0.6$

$$x_T = 2 p_T / \sqrt{s}$$

x_T and p_T have both advantages, p_T lower experimental systematics due to common uncertainty on JES $\rightarrow p_T$ preferred observable

ATLAS
 $\int L dt = 0.20 \text{ pb}^{-1}$
 $\rho = \sigma_{\text{jet}}^{2.76\text{TeV}} / \sigma_{\text{jet}}^{7\text{TeV}}$
 anti- k_t , $R = 0.4$
 Data with statistical uncertainty
 Systematic uncertainties
 NLO pQCD @ non-pert. corrections
 CT10 (yellow hatched)
 MSTW 2008 (red solid)
 NNPDF 2.1 (blue dashed)
 HERAPDF 1.5 (green dotted)
 ABM 11 NLO (black dotted)

this ratio becomes sensitive to constrain PDF \rightarrow next slide

Gluon contribution to PDF

ATLAS arXiv: 1304.4739

in general well constrained by
PDF fits from HERA data
gluon momentum distribution
below $x < 0.01$ less well known

in this analysis due to large
NP uncertainties, jets below
45 GeV excluded in fits
2.76 TeV and 7 TeV considered
fully correlated in jet calibration

→ Harder gluon spectrum after including ATLAS data
As a result, sea quark momentum spectrum softer

Ratio of Jet X Sections – different R

CMS PAS SMP-13-002

$R(0.5,0.7) = \sigma(R=0.5) / \sigma(R=0.7)$ ratio of unfolded cross sections

$R=0.5$ jets show bigger deviations (not shown here) →
non-perturbative corrections needed to improve description of jets with small radii
partonshowers in modern Monte Carlo generators mimick the NP corrections well

Ratio of Jet X Sections – different N_{jet}

ATLAS CONF-2013-041

both $R_{3/2}$ and $N_{3/2}$ have sensitivity to α_s

$$R_{3/2}(p_T^{lead}) = \frac{d\sigma_{N_{jet} \geq 3} / dp_T^{lead}}{d\sigma_{N_{jet} \geq 2} / dp_T^{lead}}$$

$$N_{3/2}(p_T^{all jets}) = \frac{\sum_i (d\sigma_{N_{jet} \geq 3} / dp_{T,i})}{\sum_i (d\sigma_{N_{jet} \geq 2} / dp_{T,i})}$$

$N_{3/2}$ has lower sensitivity to variations in scales
 → used to determine α_s shown on next slide

Determination of Running of α_s

ATLAS CONF-2013-041

arXiv: 1304.7498

ATLAS:

$$\alpha_s(M_Z) = 0.111 \pm 0.006 (\text{exp})^{+0.016}_{-0.003} (\text{theory})$$

previous measurement from CMS with similar technique:

$$\alpha_s(M_Z) = 0.1148 \pm 0.0014 (\text{exp}) \pm 0.0018 (\text{PDF})^{+0.0050}_{-0.0000} (\text{scale})$$

α_s measurement from Jet Masses

CMS SMP-12-027

$$m_3^2 = (p_1 + p_2 + p_3)^2$$

$$y_{max} = \text{sign}(|\max(y_1, y_2, y_3)| - |\min(y_1, y_2, y_3)|) \cdot \max(|y_1|, |y_2|, |y_3|)$$

unfolded spectra agree well with theory over five orders of magnitude and up to m_3 of 3 TeV

running of α_s agrees well with prediction up to $Q \sim 1.4 \text{ TeV}$

initial studies show sensitivity of m_3 to gluon distribution between $0.05 < x < 0.5$

$$\alpha_s(M_Z) = 0.1160^{+0.0025}_{-0.0023} (\text{exp, PDF, NP})^{+0.0068}_{-0.0021} (\text{scale})$$

k_T splitting scales in $W \rightarrow lv$

ATLAS Eur. Phys. J. C (2013) 73:2432

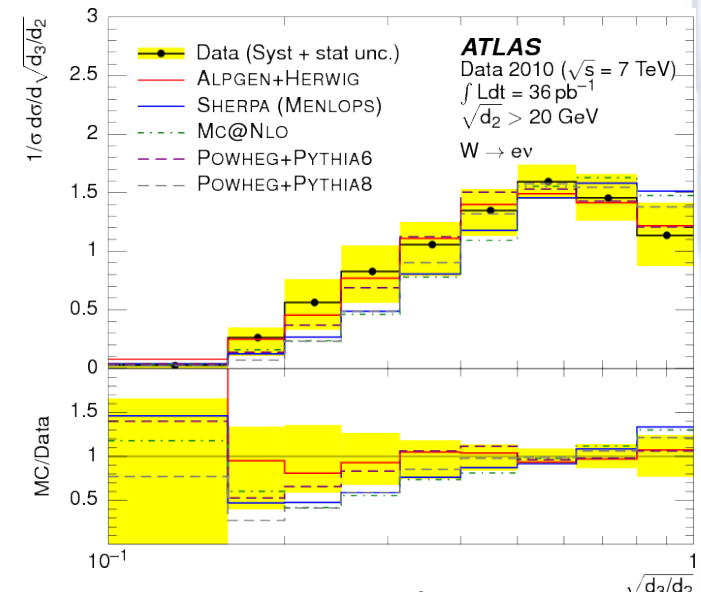

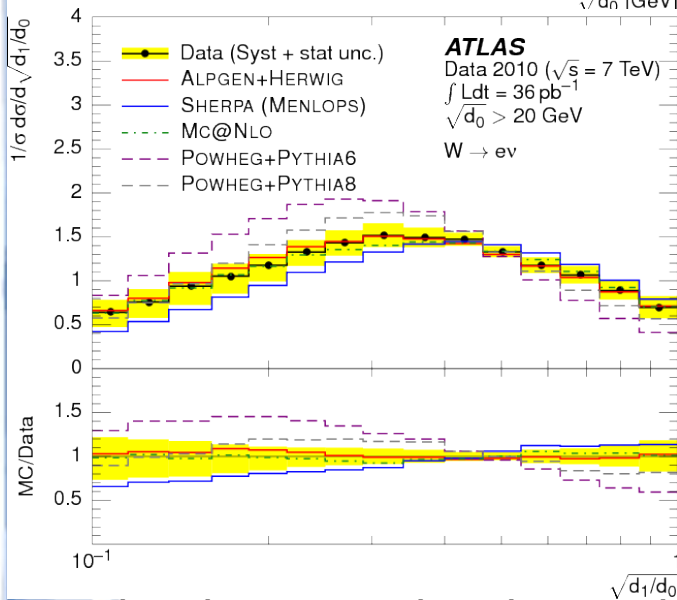

k_T jet algorithm:

$$d_{ij} = \min(p_{T_i}^2, p_{T_j}^2) \frac{\Delta R_{ij}^2}{R^2} \quad \Delta R_{ij}^2 = (y_i - y_j)^2 + (\phi_i - \phi_j)^2$$

$$d_{iB} = p_{T_i}^2$$

k_T recombination approximates QCD evolution

partial cancelation of systematic uncertainties in ratio of splitting scales

hard QCD regime better described by multi-leg generators ALPGEN+HERWIG / SHERPA
HERWIG PS gives better description for $\sqrt{d1/d0}$ (two hardest branchings)

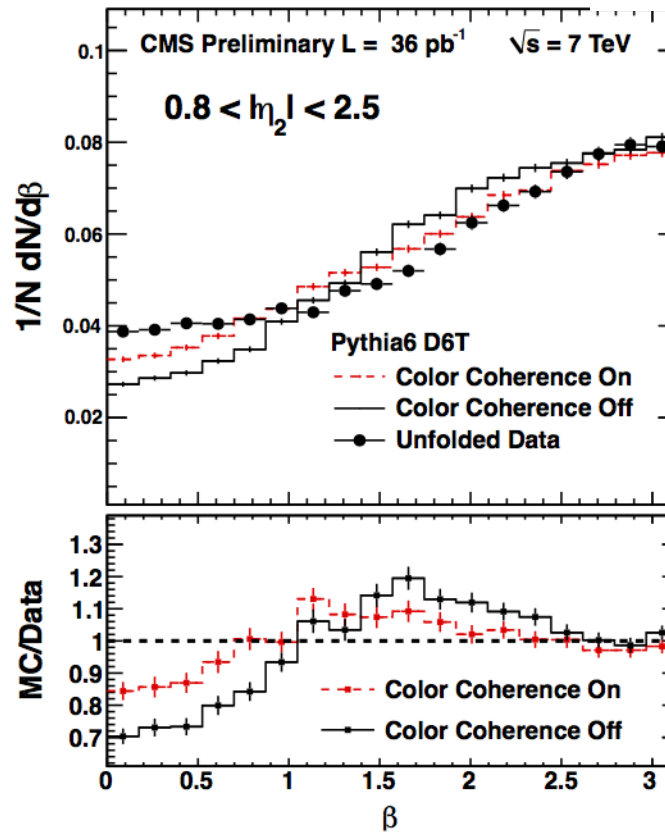

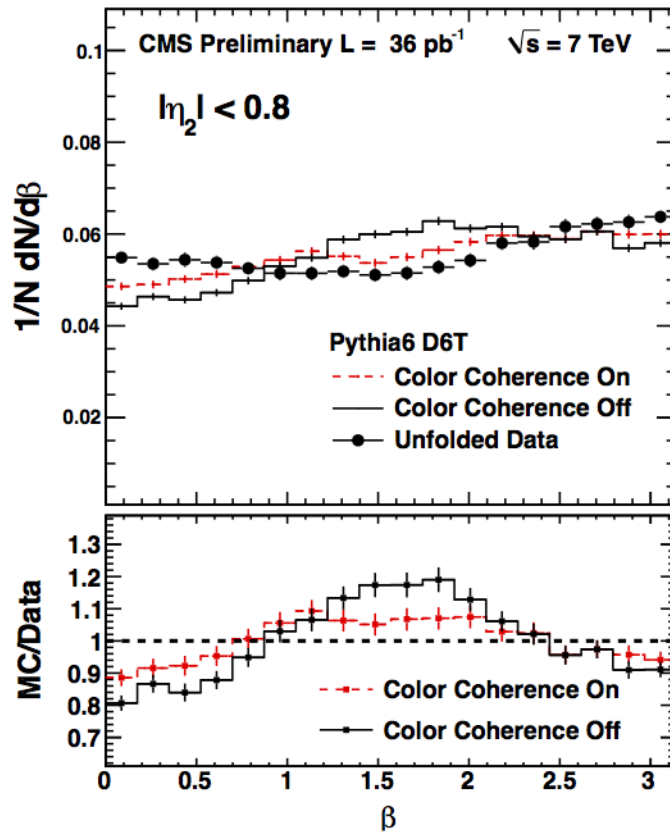

Colour Coherence

CMS PAS-SMP-12-010

$$\beta = |\text{atan2}(\Delta\Phi_{23}, \Delta\eta_{23})|$$

anti-kT with R=0.5

colour coherence suppresses particle emission around $\pi/2$ and enhances emission at 0, π

→ colour coherence in MC improves description, but still does not describe it fully
can be used for new tuning of MC to further improve description

Flavour Composition of Di-Jets

ATLAS Eur. Phys. J. C (2013) 73:2301

classify jets according to initial flavour: light quarks (U) and heavy quarks (C) and (B)
6 combinations for di-jets BB, CC, UU and mixed CU, BU, BC
create 2D templates in two kinematic variables for found vertices in jets and fit simultaneously all 6 combinations

good agreement between data and MC prediction for all 6 combinations except BU which is higher for $p_T > 100$ GeV than LO and NLO MC predictions

Jet Shapes in Light & b Quark Jets

ATLAS arXiv: 1307.5749

1.8 fb⁻¹ collected beginning of 2011

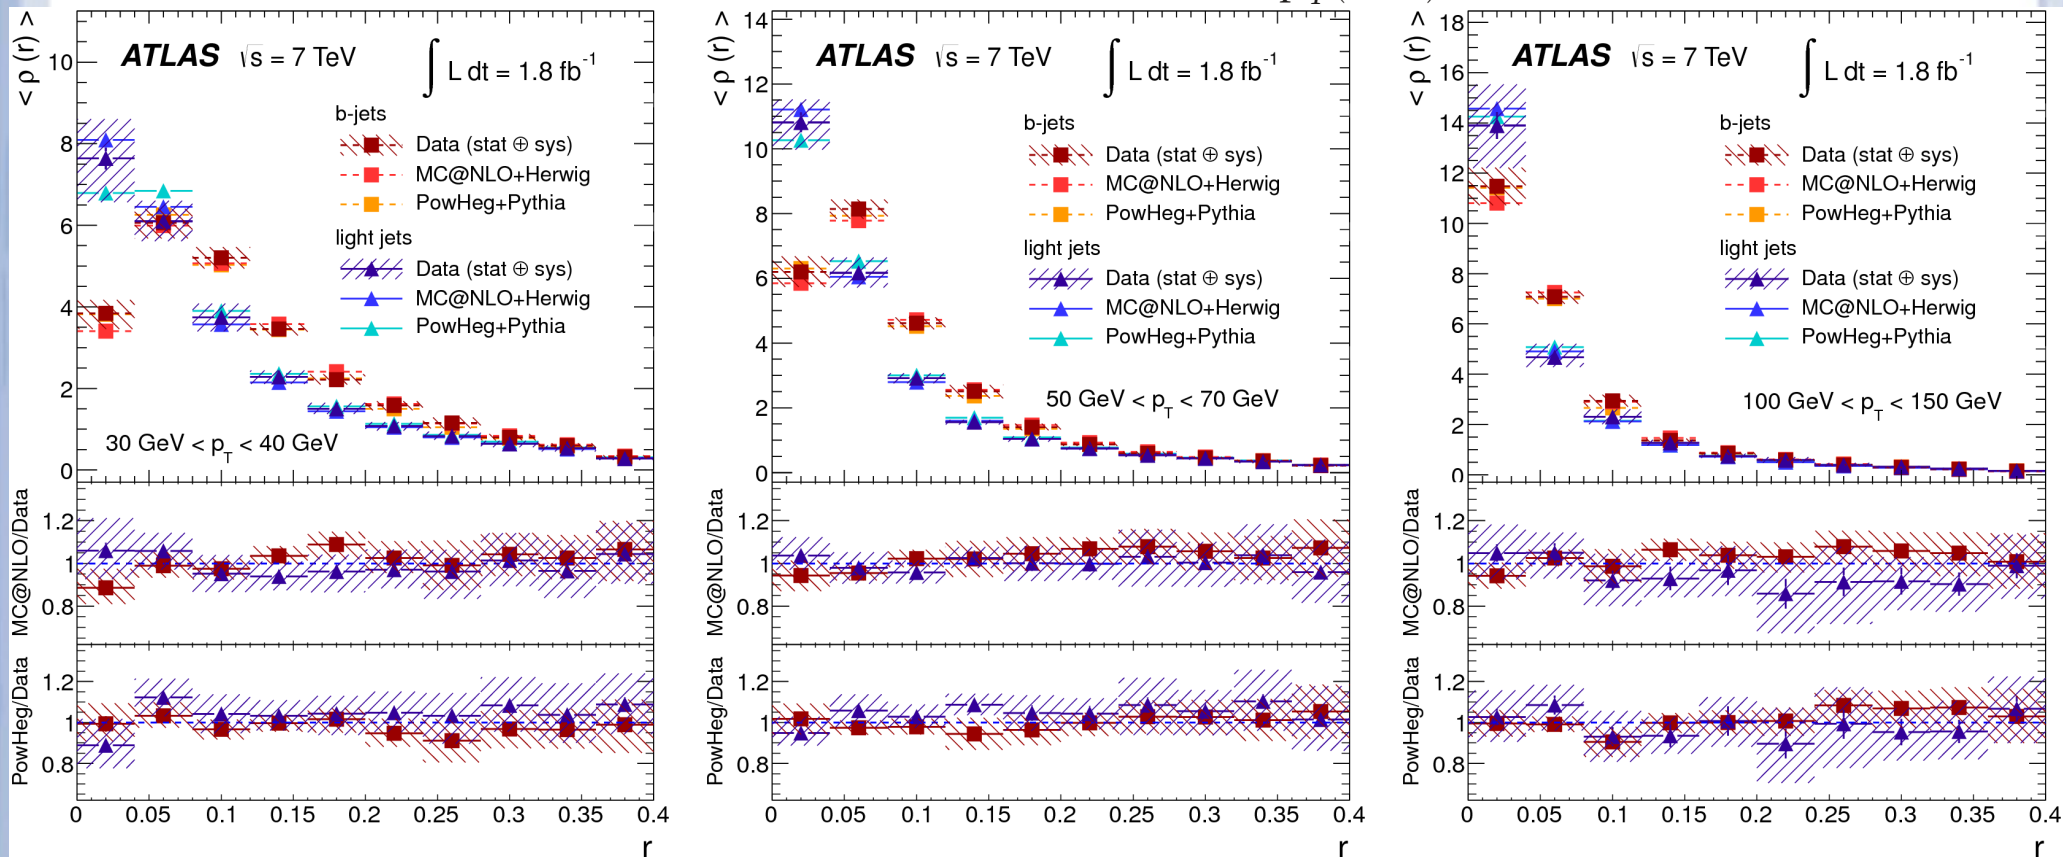

use tt events as source of clean b (from t) and light (from W) jets;

di-lepton and single-lepton channels show compatible results and were combined

mild dependence on pseudorapidity of jet; strong dependence on p_T of jet

calculate differential jet shape:

$$\rho(r) = \frac{1}{\Delta r} \cdot \frac{p_T(r - \Delta r/2, r + \Delta r/2)}{p_T(0, R)}$$

→ light jets are narrower than b-jets and is more pronounced at low jet p_T

well MC description of the measurement

Other, New Results not shown

- Jet Substructure

- grooming, trimming, more aimed pileup suppression as well as searches and investigating heavy particles

ATLAS: arXiv: 1306.4945 (submitted to JHEP)

CMS: JHEP 05 (2013) 090

- other Vector Boson + Jets

- complete list of (all) publications available at:

CMS: <https://twiki.cern.ch/twiki/bin/view/CMSPublic/PhysicsResultsSMP>

Summary and Conclusions

- many interesting new results in QCD
- in general good agreement with theory predictions
 - few exceptions e.g. heavy and light flavour QCD production
- running of strong coupling constant confirmed well above 1 TeV scale
- QCD well understood at LHC !
