The Epoch of Reionization

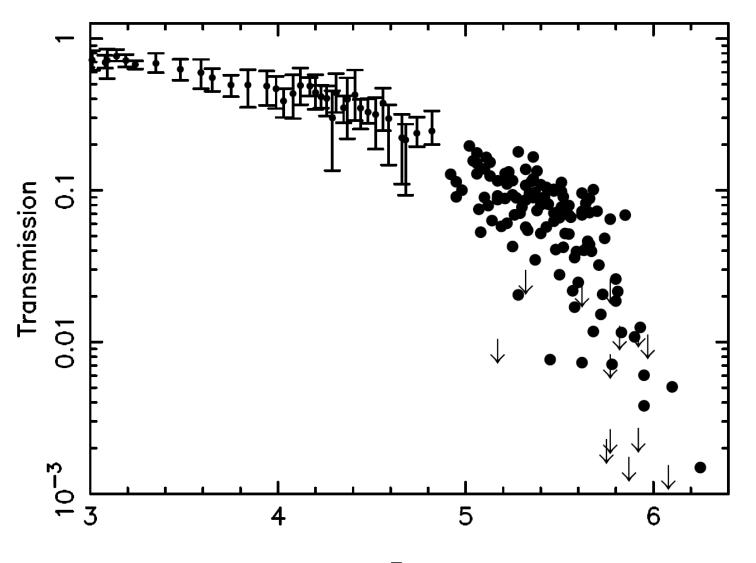

- Absorption spectra of quasars have long shown that the intergalactic medium at redshifts z < 6 is highly ionized, with a residual neutral H atom concentration of less than 1 atom in 10^4 .
 - ===> universe experienced an "epoch of reionization" before this.
- Sloan Digital Sky Survey quasars have been observed at
 z > 6 whose absorption spectra show dramatic increase in the H I
 fraction at this epoch as we look back in time.
 - ===> epoch of reionization only just ended at $z \ge 6$.

SDSS quasars show Lyman α opacity of intergalactic medium rises with increasing redshift at $z = 6 \rightarrow IGM$ more neutral \rightarrow reionization just ending?

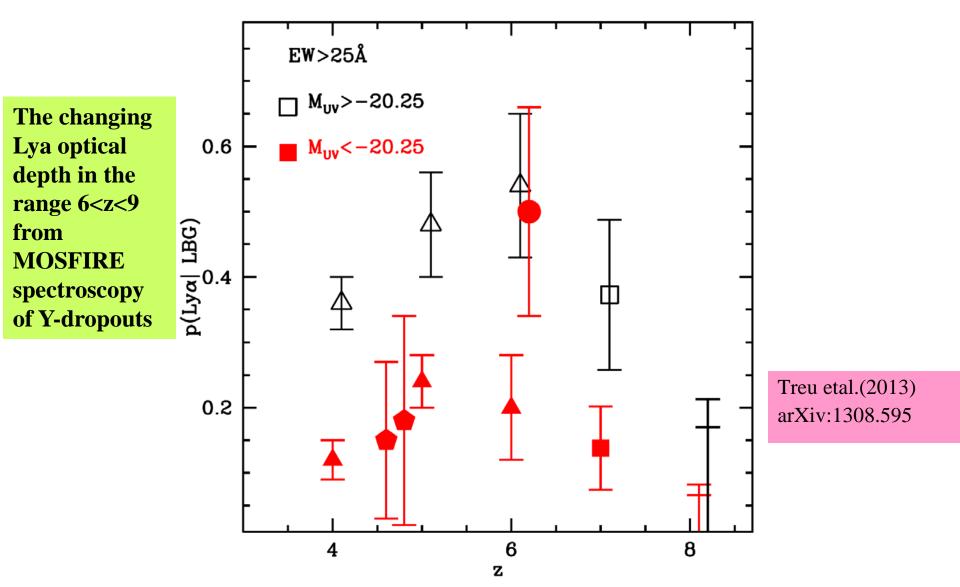

Fan et al (2005)

SDSS quasars show Lyman α opacity of intergalactic medium rises with increasing redshift at $z = 6 \rightarrow IGM$ more neutral \rightarrow reionization just ending?

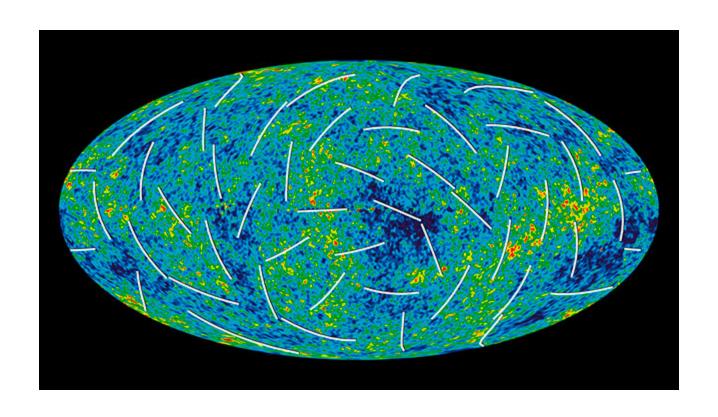

Fan et al (2006)

Fraction of Lyman-Break Galaxies (LBGs) which are Lyman α emitters (LAEs) decreases from z = 6 to $8 \rightarrow$ Lyman α opacity of intergalactic medium rises with increasing redshift at $z = 6 \rightarrow$ IGM more neutral \rightarrow reionization just ending?

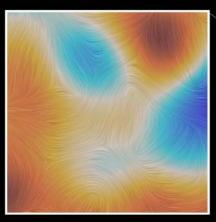

WMAP satellite mapped the pattern of polarization of the cosmic microwave background radiation across the sky ←→ light was scattered as it travelled across the universe, by intergalactic electrons

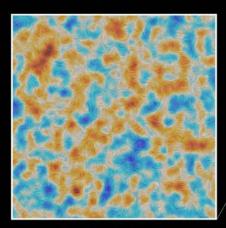

Planck satellite mapped the pattern of polarization of the cosmic microwave background radiation across the sky ← → light was scattered as it travelled across the universe, by intergalactic electrons

→ PLANCK'S POLARISATION OF THE COSMIC MICROWAVE BACKGROUND

The Epoch of Reionization

- Absorption spectra of quasars have long shown that the intergalactic medium at redshifts z < 6 is highly ionized, with a residual neutral H atom concentration of less than 1 atom in 10^4 .
 - ===> universe experienced an "epoch of reionization" before this.
- Sloan Digital Sky Survey quasars have been observed at
 z > 6 whose absorption spectra show dramatic increase in the H I
 fraction at this epoch as we look back in time.
 - ===> epoch of reionization only just ended at $z \ge 6$.
- The cosmic microwave background (CMB) exhibits polarization which fluctuates on large angular scales; *Planck* finds that almost 7% of the CMB photons were scattered by free electrons in the IGM, but only 4% could have been scattered by the IGM at z < 6.
 - ===> IGM must have been ionized earlier than z=6 to supply enough electron scattering optical depth
 - ===> reionization already substantial by $z \ge 9$

EoR Probes the Primordial Power Spectrum Down to Very Small Scales

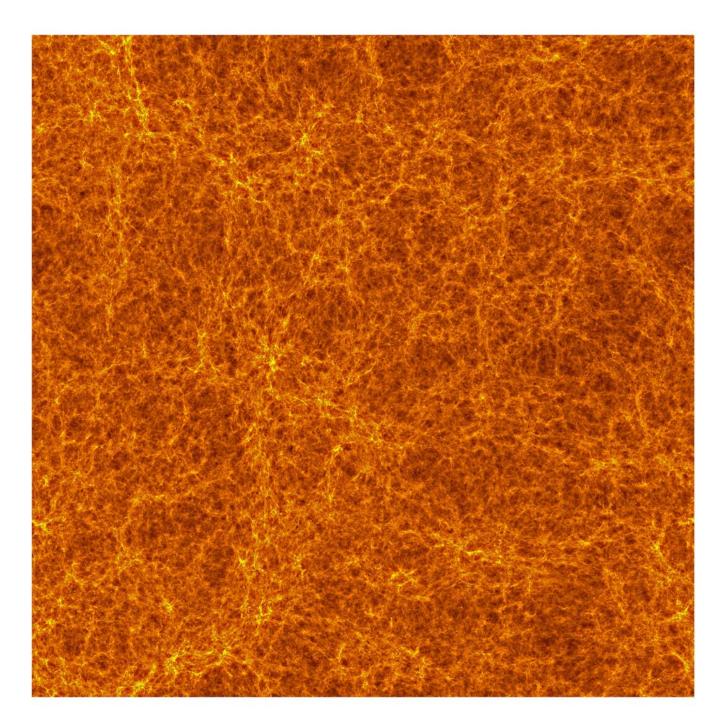

Structure formation in Λ CDM at z = 10

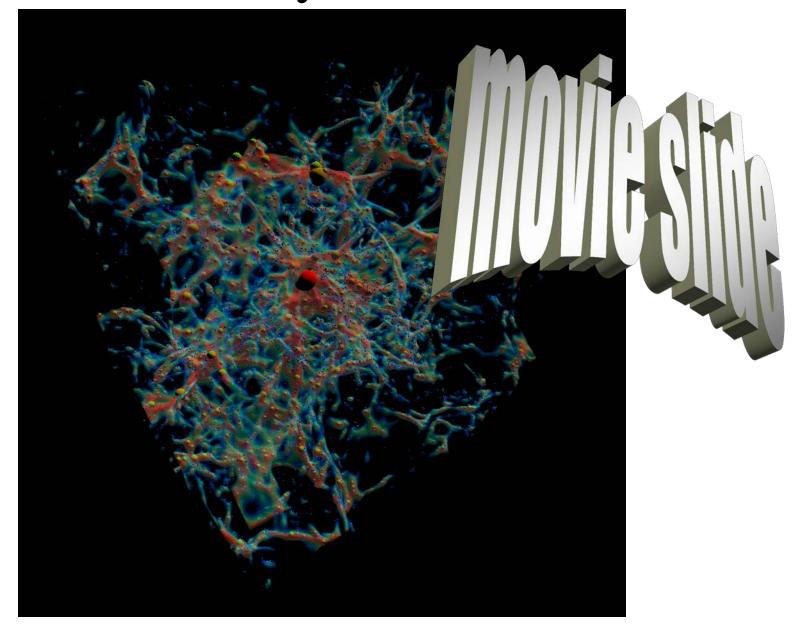

simulation volume = (100 h⁻¹Mpc)³, comoving

1624³ particles on 3248³ cells

Projection of cloud-in-cell densities of 20 Mpc slice

A Dwarf Galaxy Turns on at z=9

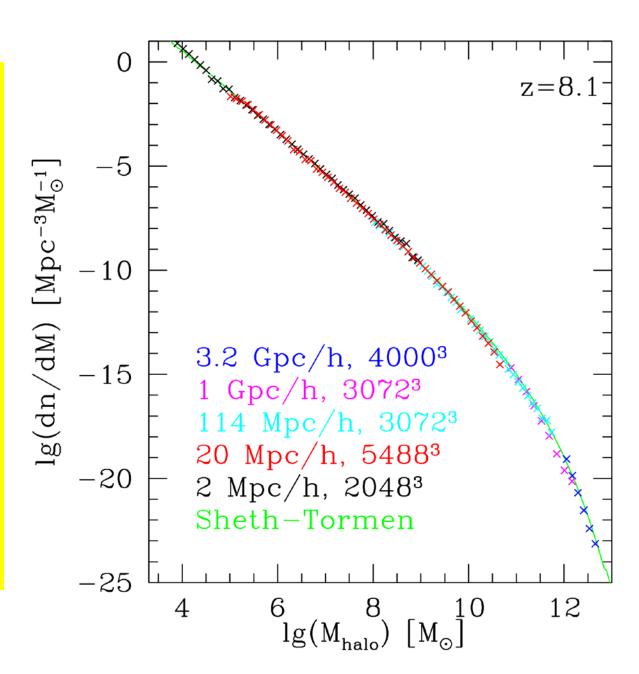

N-body + Radiative Transfer → Reionization simulation

N-body simulation yields the density field and sources of ionizing radiation

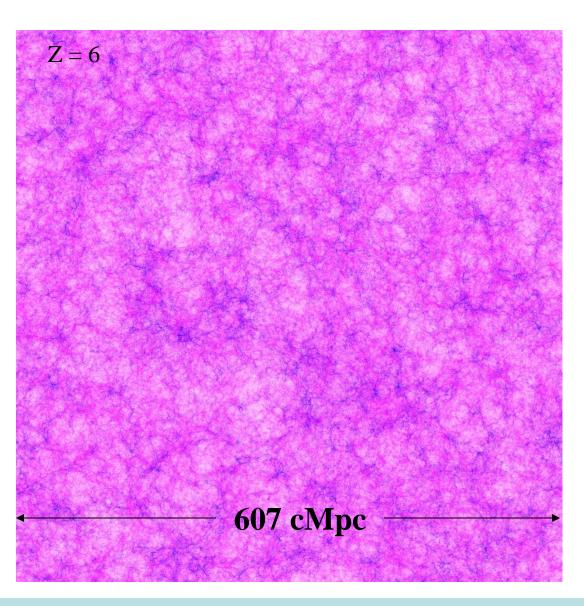

```
- New: 2<sup>nd</sup> generation N-body code CUBEP<sup>3</sup>M,
  a P<sup>3</sup>M code, massively paralleled (MPI+Open MP),
       3072^3 = 29 billion particles, 6,144<sup>3</sup> cells,
       particle mass = 5 \times 10^6 M_{solar} (163 Mpc box),
    +
       5488^3 = 165 billion particles, 10,976^3 cells,
            particle mass = 5 \times 10^3 M_{solar} (30 \text{ Mpc box}),
            particle mass = 5 \times 10^7 M_{solar} (607 Mpc box),
 - Halo finder "on-the-fly" yields location, mass, other
properties of all galaxies,
   M \ge 10^5 M_{solar}(30 \text{ Mpc box}), 10^8 M_{solar}(163 \text{ Mpc box}),
                          10<sup>9</sup> M<sub>solar</sub> (607 Mpc box)
```

Halo mass function now simulated for **LCDM** over full mass range from **IGM Jeans** mass before EOR to the largest halos that form during the **EOR**

Largest Volume N-body Simulation for Reionization : (607 cMpc)³

- CUBEP³M 5488³ = 165 billion particles 10, 976³ cells
- •Resolves all halos with $M \geq \ 10^9 \ M_{sun}$
- •First halos form at z = 26
- 4×10^7 halos by z = 8
- $\sim 2 \times 10^8$ halos by z = 2.5
- IGM density = violet halos = blue

N-body + Radiative Transfer -> Reionization simulation

- Radiative transfer simulations evolve the radiation field and nonequilibrium ionization state of the gas

 New, fast, efficient C²-Ray code (Conservative, Causal Ray-Tracing) (Mellema, Iliev, Alvarez, & Shapiro 2006, New Astronomy, 11, 374) uses short-characteristics to propagate radiation throughout the evolving gas density field provided by the N-body results, on coarser grid of ~ (256)³ to (512)³ cells, for different resolution runs, from each and every galaxy halo source in the box.
- e.g. $N_{halo} \sim 4 \times 10^5$ by $z \sim 8$ (WMAP1) (> 2×10^9 M_{sun}) $\sim 3 \times 10^5$ by $z \sim 6$ (WMAP3) (> 2×10^9 M_{sun}) $\sim 10^7$ by $z \sim 8$ (WMAP5) (> 10^8 M_{sun}) for simulation volumes $\sim (100 \text{ h}^{-1} \text{ Mpc})^3$

Every galaxy in the simulation volume emits ionizing radiation

We assume a constant mass-to-light ratio for simplicity:

 f_{γ} = # ionizing photons released by each galaxy per halo baryon $\rightarrow f_{\gamma} = f_* f_{esc} N_i$,

where

 f_* = star-forming fraction of halo baryons, f_{esc} = ionizing photon escape fraction,

 N_i = # ionizing photons emitted per stellar baryon over stellar lifetime e.g.

 $N_i = 50,000$ (top-heavy IMF), $f_* = 0.2$, $f_{esc} = 0.2 \implies f_{\gamma} = 2000$ or

 $N_i = 4,000$ (Salpeter IMF), $f_* = 0.1$, $f_{esc} = 0.1 \rightarrow f_{\gamma} = 40$

• This yields source luminosity: $dN_{\gamma}/dt = f_{\gamma} M_{bary} / (\mu m_{H} \Delta t_{*})$, $\Delta t_{*} = source$ lifetime (e.g. 2 x 10⁷ yrs), $M_{bary} = halo$ baryonic mass = $M_{halo} * (\Omega_{bary} / \Omega_{m})$ \rightarrow halo star formation rate: SFR = $(f_{\gamma} / \Delta t_{*})(M_{bary} / f_{esc} N_{i})$

Every galaxy in the simulation volume emits ionizing radiation

We assume a constant mass-to-light ratio for simplicity:

 f_{γ} = # ionizing photons released by each galaxy per halo baryon \rightarrow $f_{\gamma} = f_{*}$ f_{esc} N_{i} ,

where

 f_* = star-forming fraction of halo baryons, f_{esc} = ionizing photon escape fraction,

 N_i = # ionizing photons emitted per stellar baryon over stellar lifetime e.g.

 $N_i = 50,000$ (top-heavy IMF), $f_* = 0.2$, $f_{esc} = 0.2 \implies f_{\gamma} = 2000$ or

 $N_i = 4,000$ (Salpeter IMF), $f_* = 0.1$, $f_{esc} = 0.1 \implies f_{\gamma} = 40$

→ halo star formation rate: SFR = $(f_{\gamma} / \Delta t_{*})(M_{bary} / f_{esc} N_{i})$

SFR \cong 1.7 (f_{\gamma}/40) (0.1/f_{esc}) (4000/N_i) (10 Myr/ Δt_*) (M_{halo}/10⁹ M_{solar}) M_{solar}/ yr e.g. f_{\gamma} = 40, f_{esc} = 0.1, f_{*} = 0.1, Δt_* = 2 x 10⁷ yrs \Rightarrow SFR \cong (0.8 M_{solar}/yr) * (M_{halo}/10⁹ M_{solar})

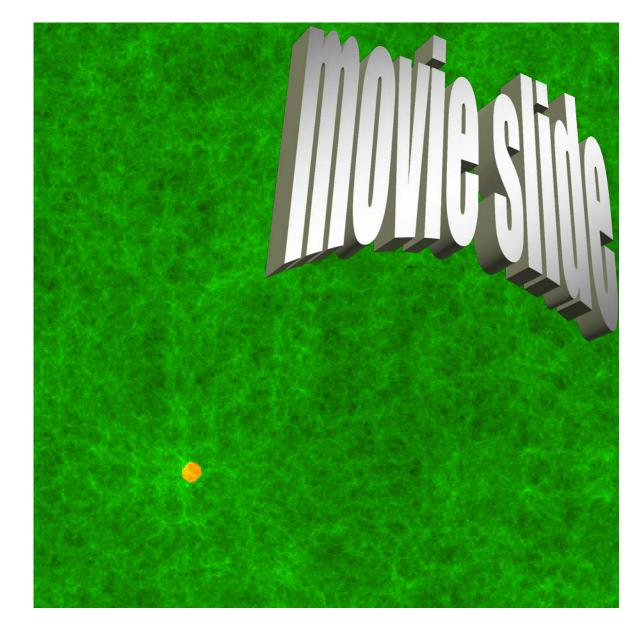

Self-Regulated Reionization

Iliev, Mellema, Shapiro, & Pen (2007), MNRAS, 376, 534; (astro-ph/0607517)

•Jeans-mass filtering →
low-mass source halos
(M < 10⁹ M_{solar}) cannot form
inside H II regions;

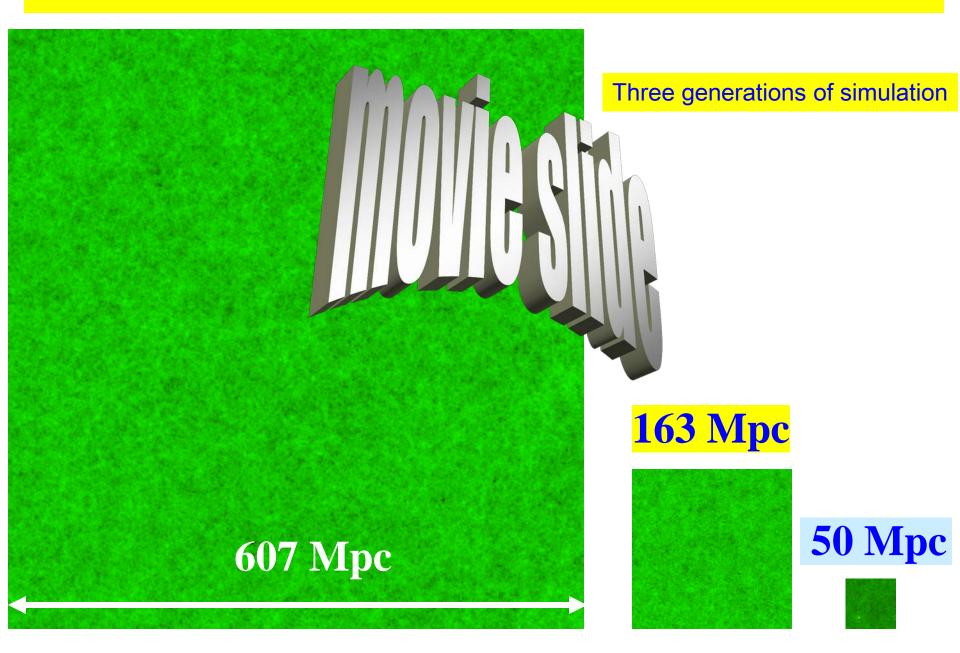

•35/h Mpc box, 406^3 radiative transfer simulation, WMAP3, $f_{\gamma} = 250$;

•resolved all halos with $M > 10^8 M_{solar}$ (i.e. all atomically-cooling halos), (blue dots = source cells);

• Evolution: z=21 to $z_{ov} = 7.5$.

Large-scale, self-regulated reionization by atomic-cooling halos

white4.wmv

Q: Are there observable consequences of reionization we can predict which will allow us to determine which of these sources contribute most significantly to reionization?

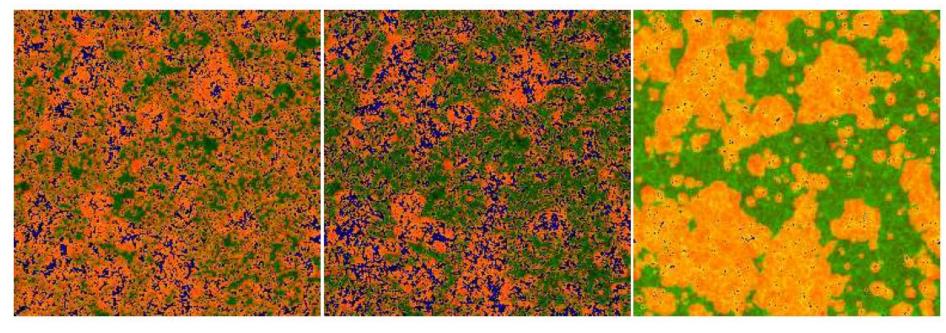

A: Radiation backgrounds from the EoR, including:

- 1. 21cm
- 2. Near-IR
- 3. CMB (polarization & kinetic Sunyaev-Zel'dovich)

Can 21-cm Observations Discriminate Between High-Mass and Low-Mass Galaxies as Reionization Sources?

Iliev, Mellema, Shapiro, Pen, Mao, Koda, & Ahn 2012, MNRAS, 423, 2222 (arXiv: 1107.4772)

163 Mpc boxes at the 50% ionized epoch

High efficiency = early reionization

Low efficiency = late reionization

High efficiency = early reionization

HMACHs + LMACHs

HMACHs only

Low-Mass Atomic Cooling Halos, or *LMACHs* $\rightarrow 10^8 < M < 10^9 M_{solar}$

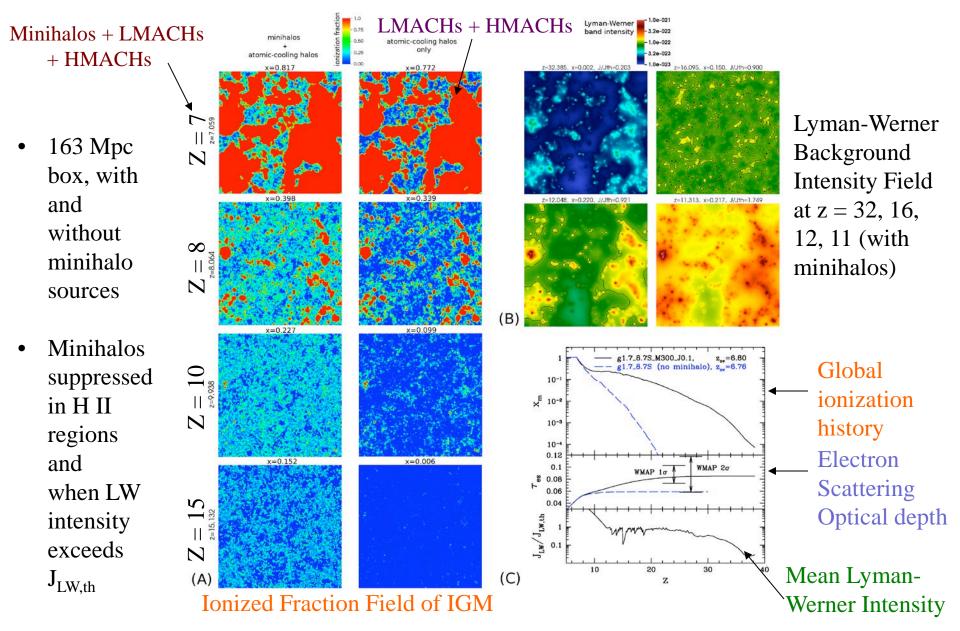

High-Mass Atomic Cooling Halos, or *HMACHs*

 \rightarrow M > 10^9 M_{solar}

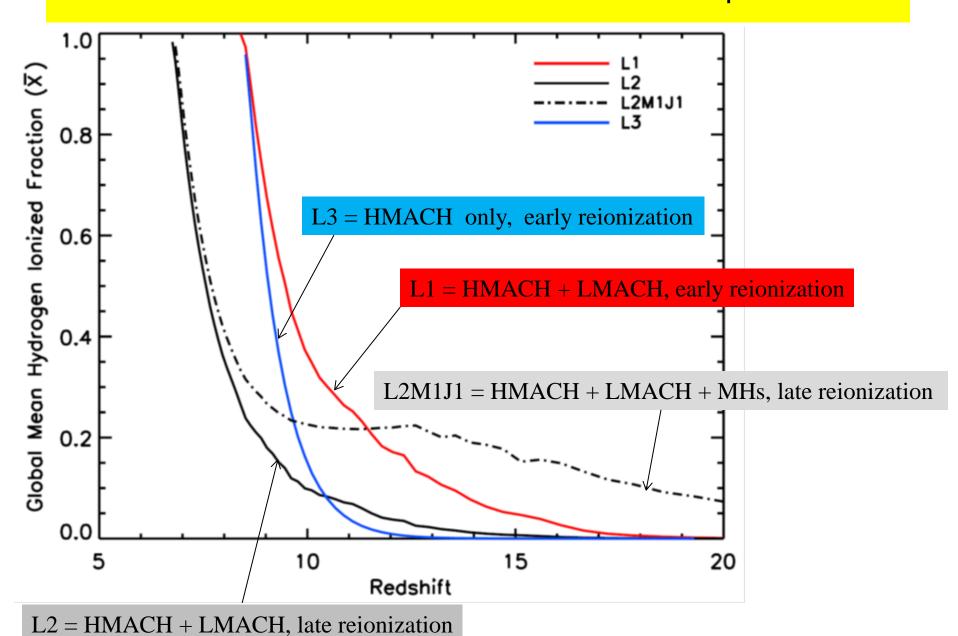

(suppressed inside H II regions by photoheating)

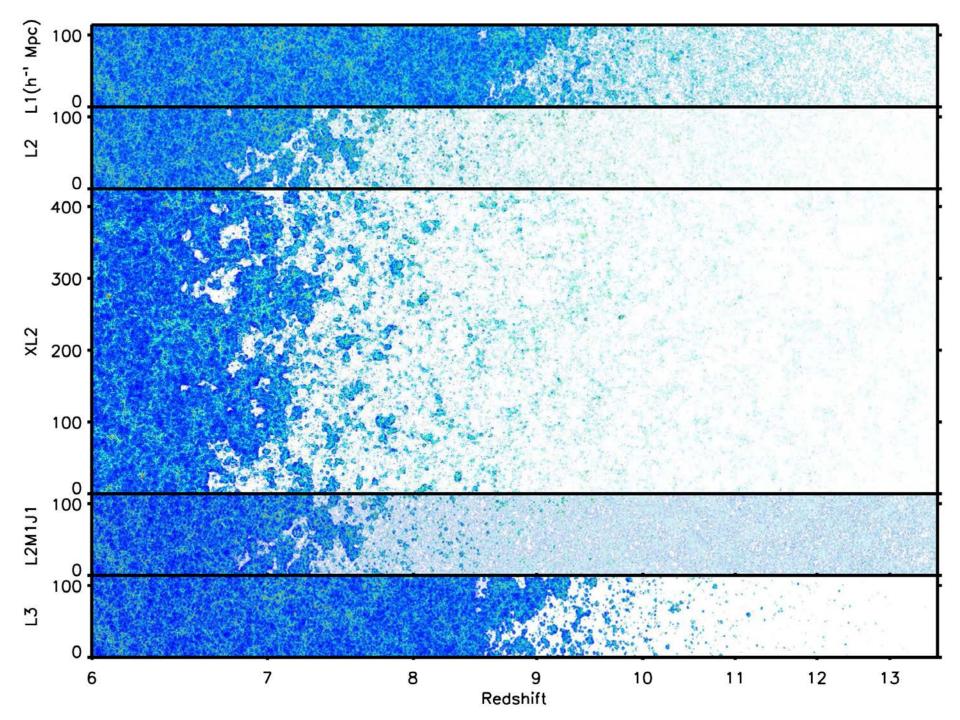

Effects of the First Stars and Minihalos on Reionization

Ahn, Iliev, Shapiro, Mellema, Koda, and Mao (2012) ApJL, 756, L16

Four reionization simulation cases for comparison

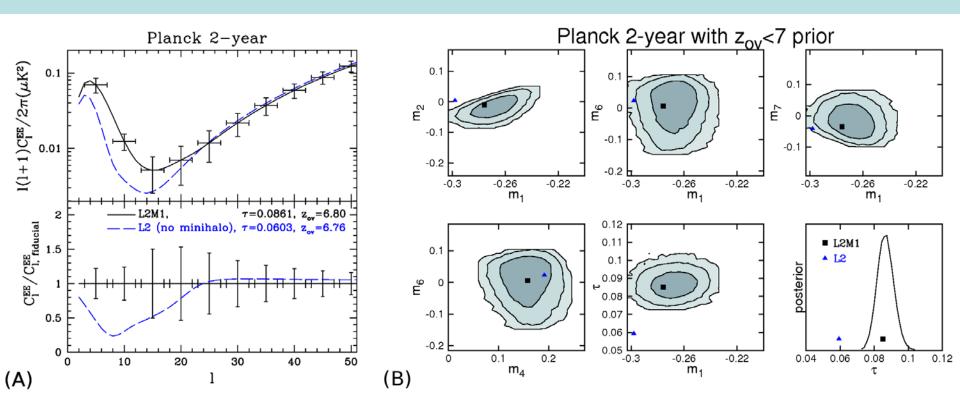

CMB polarization fluctuations at large angular scales may probe the effects of the first stars and minihalos on reionization

Ahn, Iliev, Shapiro, Mellema, Koda, and Mao (2012) ApJL, 756, L16

Prediction:

- With minihalo sources, reionization began much earlier and was greatly extended, which boosts the intergalactic electron-scattering optical depth and large-angle polarization fluctuations of the CMB significantly.
- If reionization ended as late as $z \sim 7$, as suggested by other observations, *Planck* will thereby see the signature of the first stars at high redshift, currently undetectable by any other probe

The Kinetic Sunyaev-Zel'dovich Effect from Patchy Reionization as a Cosmological Probe

Park, Shapiro, Komatsu, Iliev, Ahn, Mellema (2013), ApJ, 769, 93

 kSZ effect is the CMB temperature anisotropy induced by electron scattering by free electrons moving along the line-of-sight.

$$\frac{\Delta T}{T_{\rm CMB}} = \int d\eta e^{-\tau_{\rm es}(\eta)} a n_e \sigma_T \mathbf{n} \cdot \mathbf{v},$$

where η is conformal time,

$$\eta = \int_0^t dt'/a(t')$$

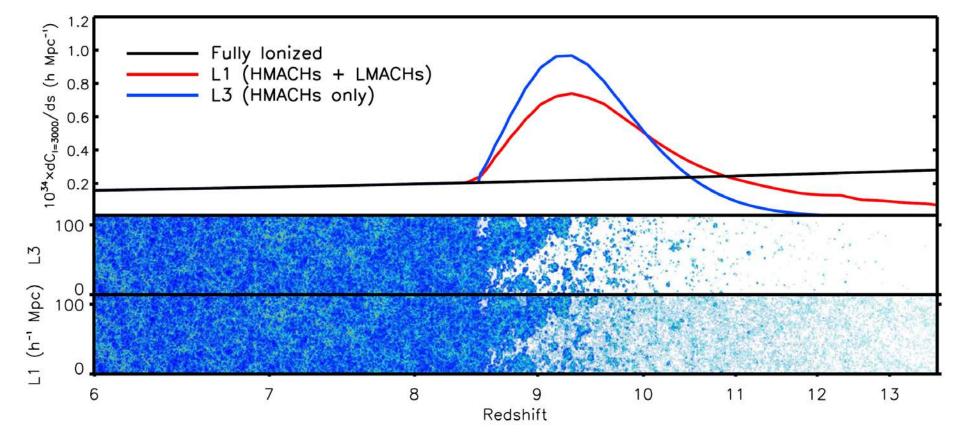

Contributions to kSZ from different redshifts: post-reionization + patchy reionization → different source models distinguishable?

The Redshifted 21cm Signal From the EoR

 The measured radio signal is the differential brightness temperature

•
$$\delta T_b = T_b - T_{CMB}$$
: $\delta T_b = 28.74 \ x_{HI} (1 + \delta) \left(\frac{1+z}{10}\right)^{1/2} \left[1 - \frac{T_{CMB}(z)}{T_s}\right] \left[1 + \left(\frac{1+z}{H(z)}\right) \frac{dv_{\parallel}}{dr_{\parallel}}\right]^{-1} \text{ mK}$

(for WMAP7 cosmological parameters).

- Depends on:
 - x_{HI}: neutral fraction
 - δ: overdensity
 - T_s: spin temperature
- For T_s»T_{CMB}, the dependence on T_s drops out
- The signal is a spectral *line*: carries spatial, temporal, and velocity information.

$$u = rac{
u_0}{1+z_{
m obs}} \qquad ext{and} \qquad z_{
m obs} = (1+z)(1+rac{v_\parallel}{c})-1$$

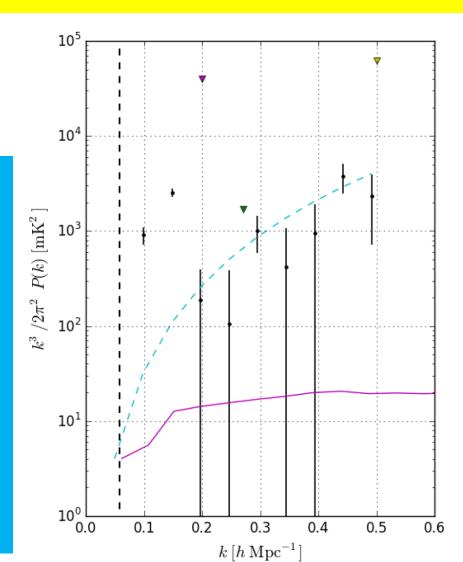

The image cube: images stacked in frequency space

New limit on 21cm power spectrum at z = 8.4 from the Paper-64 EoR Experiment Ali et al. (2015) arXiv:1502.06016

135 days of data →

Consistent with IGM at z = 8.4 either fully ionized or else heated where still neutral (e.g. as if by X-rays) so $T_{spin} >> T_{CMB}$

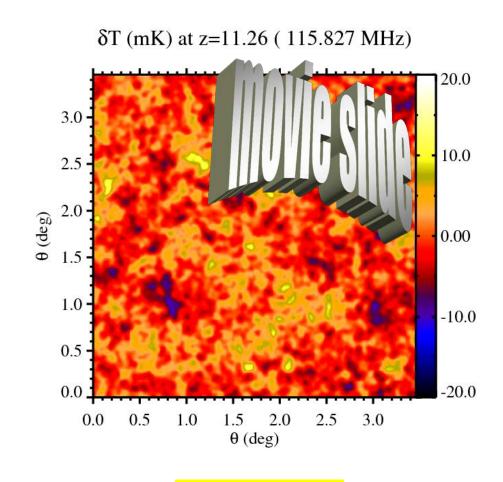

New 2σ upper limit $(22 \text{ mK})^2$ for k = 0.15 hMpc⁻¹ To k = 0.5 hMpc -1

Sky Maps of 21cm Background Brightness Temperature Fluctuations During Epoch of Reionization: Travel through Time

Iliev, Mellema, Ahn, Shapiro, Mao & Pen 2014, MNRAS, 439, 725 (arXiv:1310.7463)

- Reionization has a complex geometry of growing and overlapping HII regions.
- Here illustrated evolving redshifted 21cm signal:
 - High density neutral regions are yellow
 - lonized regions are blue/black.
- LOFAR-like beam: 3' resolution & average signal is zero.

Reionization of the Universe

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

Q: Did reionization leave an imprint on the Local Group galaxies we can observe today?

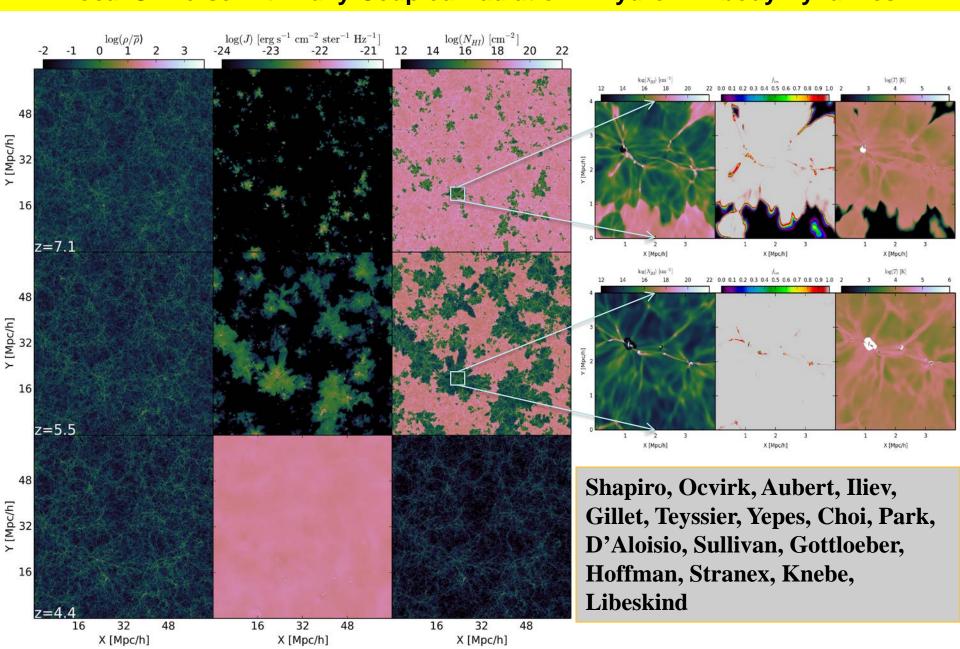

Q: Does reionization help explain why the observed number of dwarf galaxies in the Local Group is far smaller than the number of small halos predicted by ΛCDM N-body simulations?

Q: Was the Local Group ionized from within or without?

A: Simulate the coupled radiation-hydro-N-body problem of reionization → galaxy formation with ionization fronts that swept across the IGM in the first billion years of cosmic time, in a volume 91 Mpc on a side centered on the Local Group.

Introducing the CoDa (COsmic DAwn) Simulation: Reionization of the Local Universe with Fully-Coupled Radiation + Hydro + N-body Dynamics

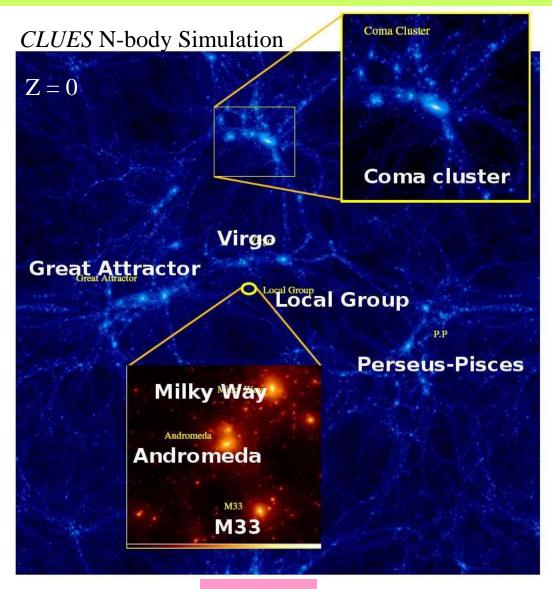

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

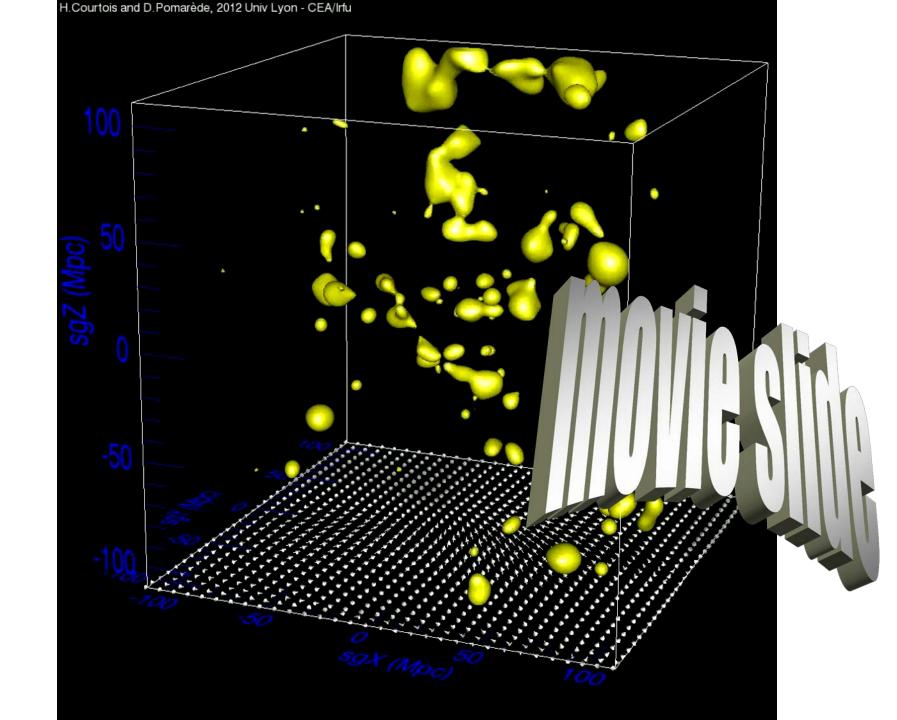

What makes this possible now?

1) Initial Conditions:

- Start from "constrained realization" of Gaussian-random-noise initial conditions, provided by our collaborators in the CLUES (Constrained Local UniversE Simulations) consortium
- This reproduces observed features of our local Universe, including the Local Group and nearby galaxy clusters.
- Add higher frequency modes for small-scale structure

229 cMpc

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

What makes this possible now?

2) New Hybrid (CPU + GPU) numerical method + New Hybrid (CPU + GPU) supercomputer

N-body + Hydro = **RAMSES** (Teyssier 2002)

- Gravity solver is Particle Mesh code with Multi-Grid Poisson solver
- Hydro solver is shock-capturing, second-order Godunov scheme on Eulerian grid

Radiative Transfer + Ionization Rate Solver = **ATON** (Aubert & Teyssier 2008)

- RT is by a moment method with M1 closure
- Explicit time integration, time-step size limited by CFL condition >

$$\Delta t < \Delta x / c$$
,

where c = speed of light

ATON \rightarrow (ATON) x (GPUs) = CUDATON (Aubert & Teyssier 2010)

•GPU acceleration by factor ~ 100

RAMSES + CUDATON = RAMSES-CUDATON

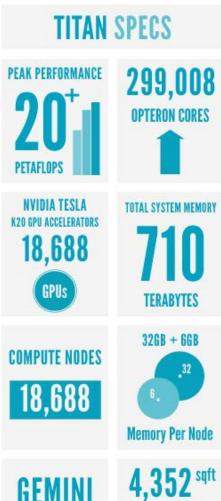

- •RT on the GPUs @ CFL condition set by speed of light
- •(hydro + gravity) on the CPUs @ CFL condition set by sound speed
- (# RT steps)/(# hydro-gravity steps) > 1000 will not slow hydro-gravity calculation

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

TITAN by the numbers:

- N-body particles $= (4096)^3$
- Min halo mass ~ 10⁸ solar masses

See a map of the ionized gas density evolve thru the EOR in another cut-out region

This cut-out is reionized by external sources, as the matter in this cut-out falls toward the source of its reionization.

Selected Cut-outs

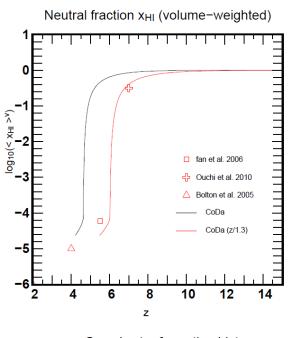

RAMSES-CUDATON simulation

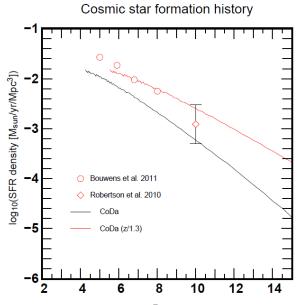

- Box size = 91 cMpc
- Grid size = $(4096)^3$ cells
- N-body particles $= (4096)^3$
- Min halo mass ~
 10⁸ solar masses

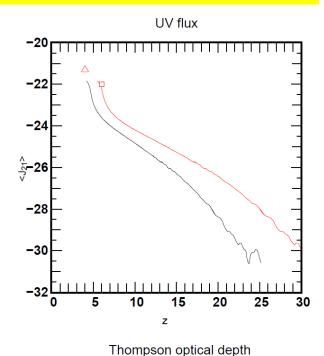

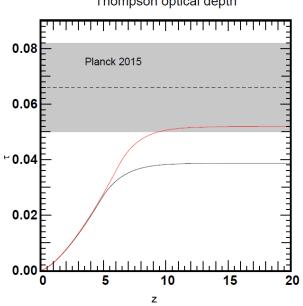

Sub-regions with reionization histories that ended gradually were reionized by *internal sources*, while those whose histories finished abruptly were reionized by *external sources*.

- Efficiencies set from smaller-box simulations prove slightly low, so reionization ends a bit late: $z_{rei} < 5$
- But if we let
 z → z * 1.3,
 there is good agreement
 with observable
 constraints

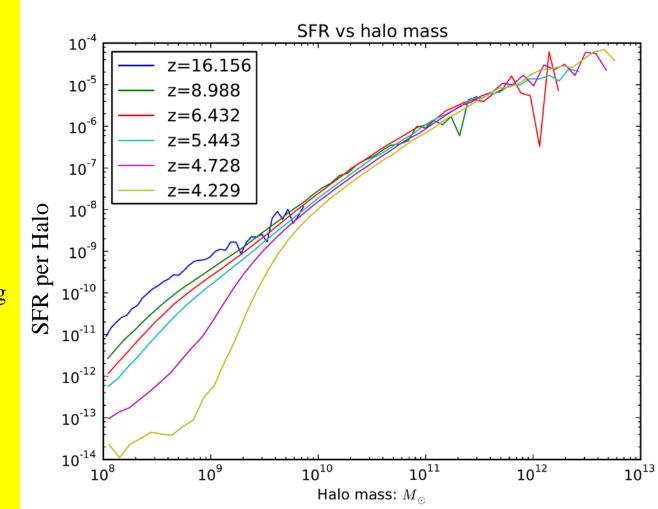

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

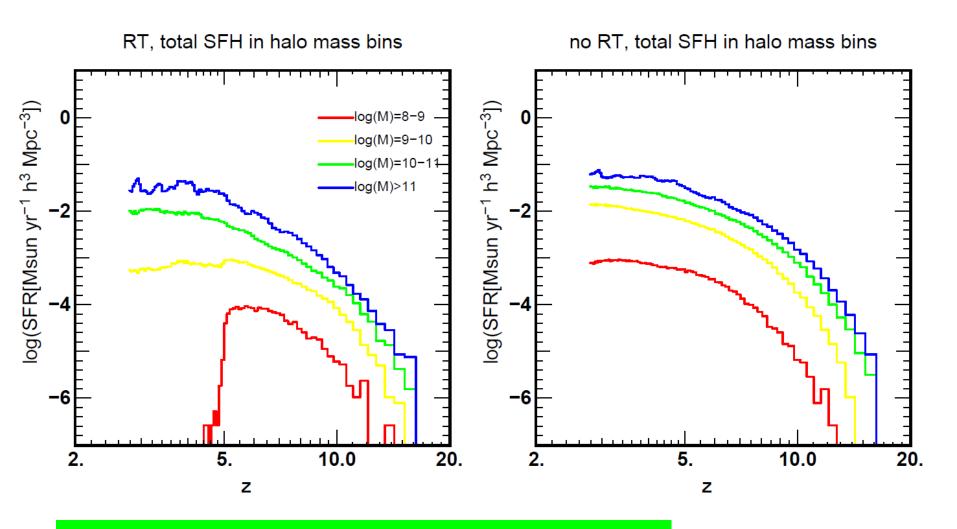

Reionization suppresses star formation rate in dwarf galaxies, for $M < 10^9$ solar masses

- photoionization-heating & SN remnant shock-heating raises gas pressure
- Gas pressure of heated gas resists gravitational binding into the low-mass galaxies
- → lowers the cold, dense baryon gas fraction
- → lowers the SFR per unit halo mass
- Low-mass atomic cooling halos (LMACHs) are most suppressed

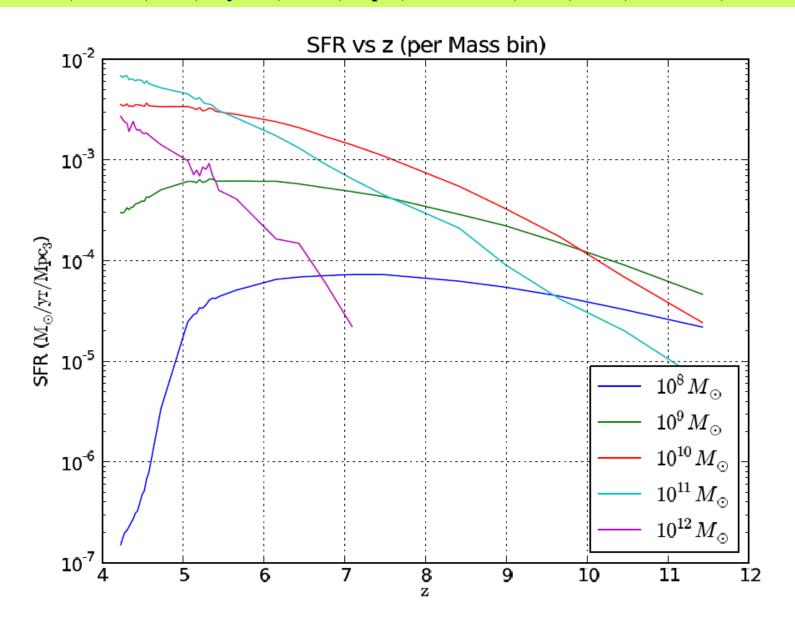

SFR \propto M $^{\alpha}$, α ~ 5/3 for M > 10 10 solar masses, but drops sharply below M ~ 3 X 10 9 below z ~ 6

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

• Star Formation Rate attributed to halo mass bins in which stars are found at a fixed late time, after reionization ends

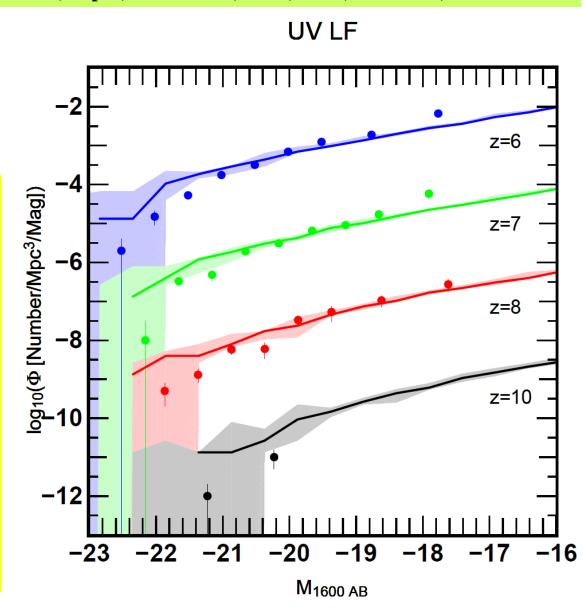

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

UV Luminosity Function
vs.
Observations from
Bouwens et al. (2014)

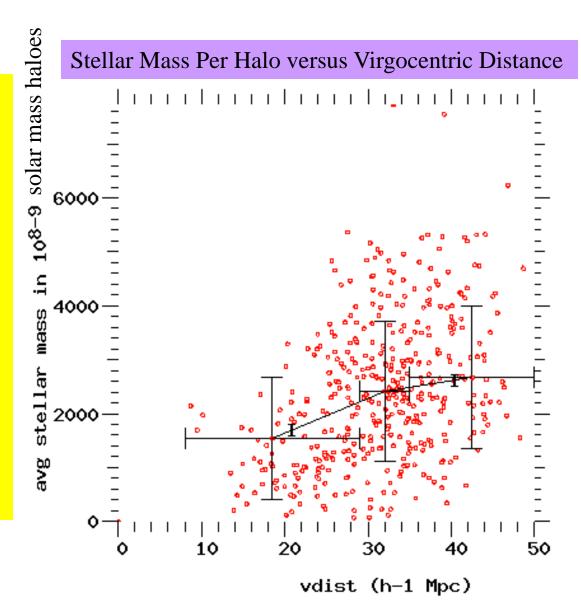

- Full circles are from Bouwens et al. (2014)
- Shaded areas and thick lines show the envelope and median of the LFs of 5 equal, independent subvolumes 50/h cMpc
- M_{AB1600} magnitudes computed using lowest metallicity SSP models of Bruzual & Charlot (2003), scaled to same ionizing photons released per 10 Myr
- Shift simulation $z \rightarrow z * 1.3$

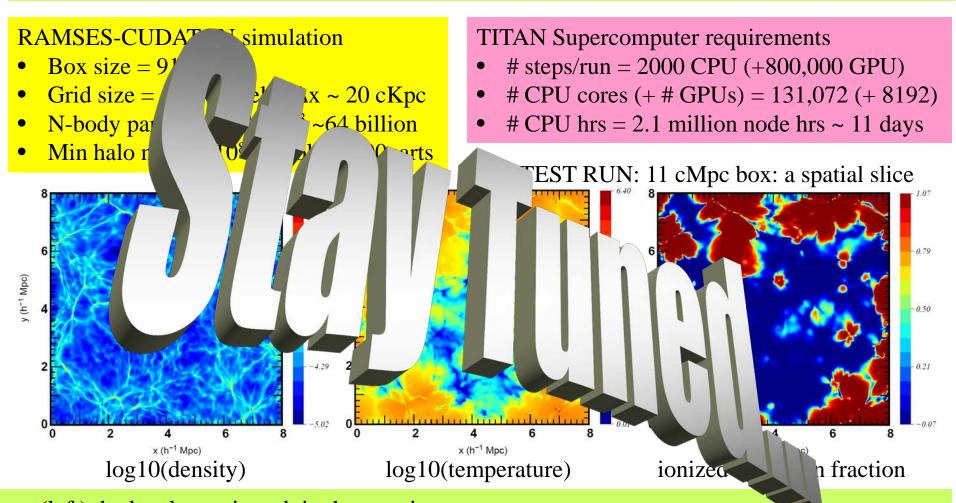

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

Reionization suppresses star formation rate in dwarf galaxies, for $M < 10^9$ solar masses

- Suppression varies with location
- Suppression decreases with increasing distance from a density peak like that which made the Virgo cluster, whose influence can extend over 10's of cMpc
- → Large-scale structure leaves an imprint on the SFR in dwarf galaxies correlated over 10's of Mpc

Shapiro, Ocvirk, Aubert, Iliev, Teyssier, Gillet, Yepes, Gottloeber, Choi, Park, D'Aloisio, Sullivan +

- (left) the local cosmic web in the atomic gas;
- (middle) red regions denote very hot, supernova-powered superbubbles, while yellow-orange regions show the long-range impact of photo-heating by starlight;
- (right) ionized hydrogen fraction [dark red (dark blue) = ionized (neutral)].

PEACE and Happy Anniversaly.
