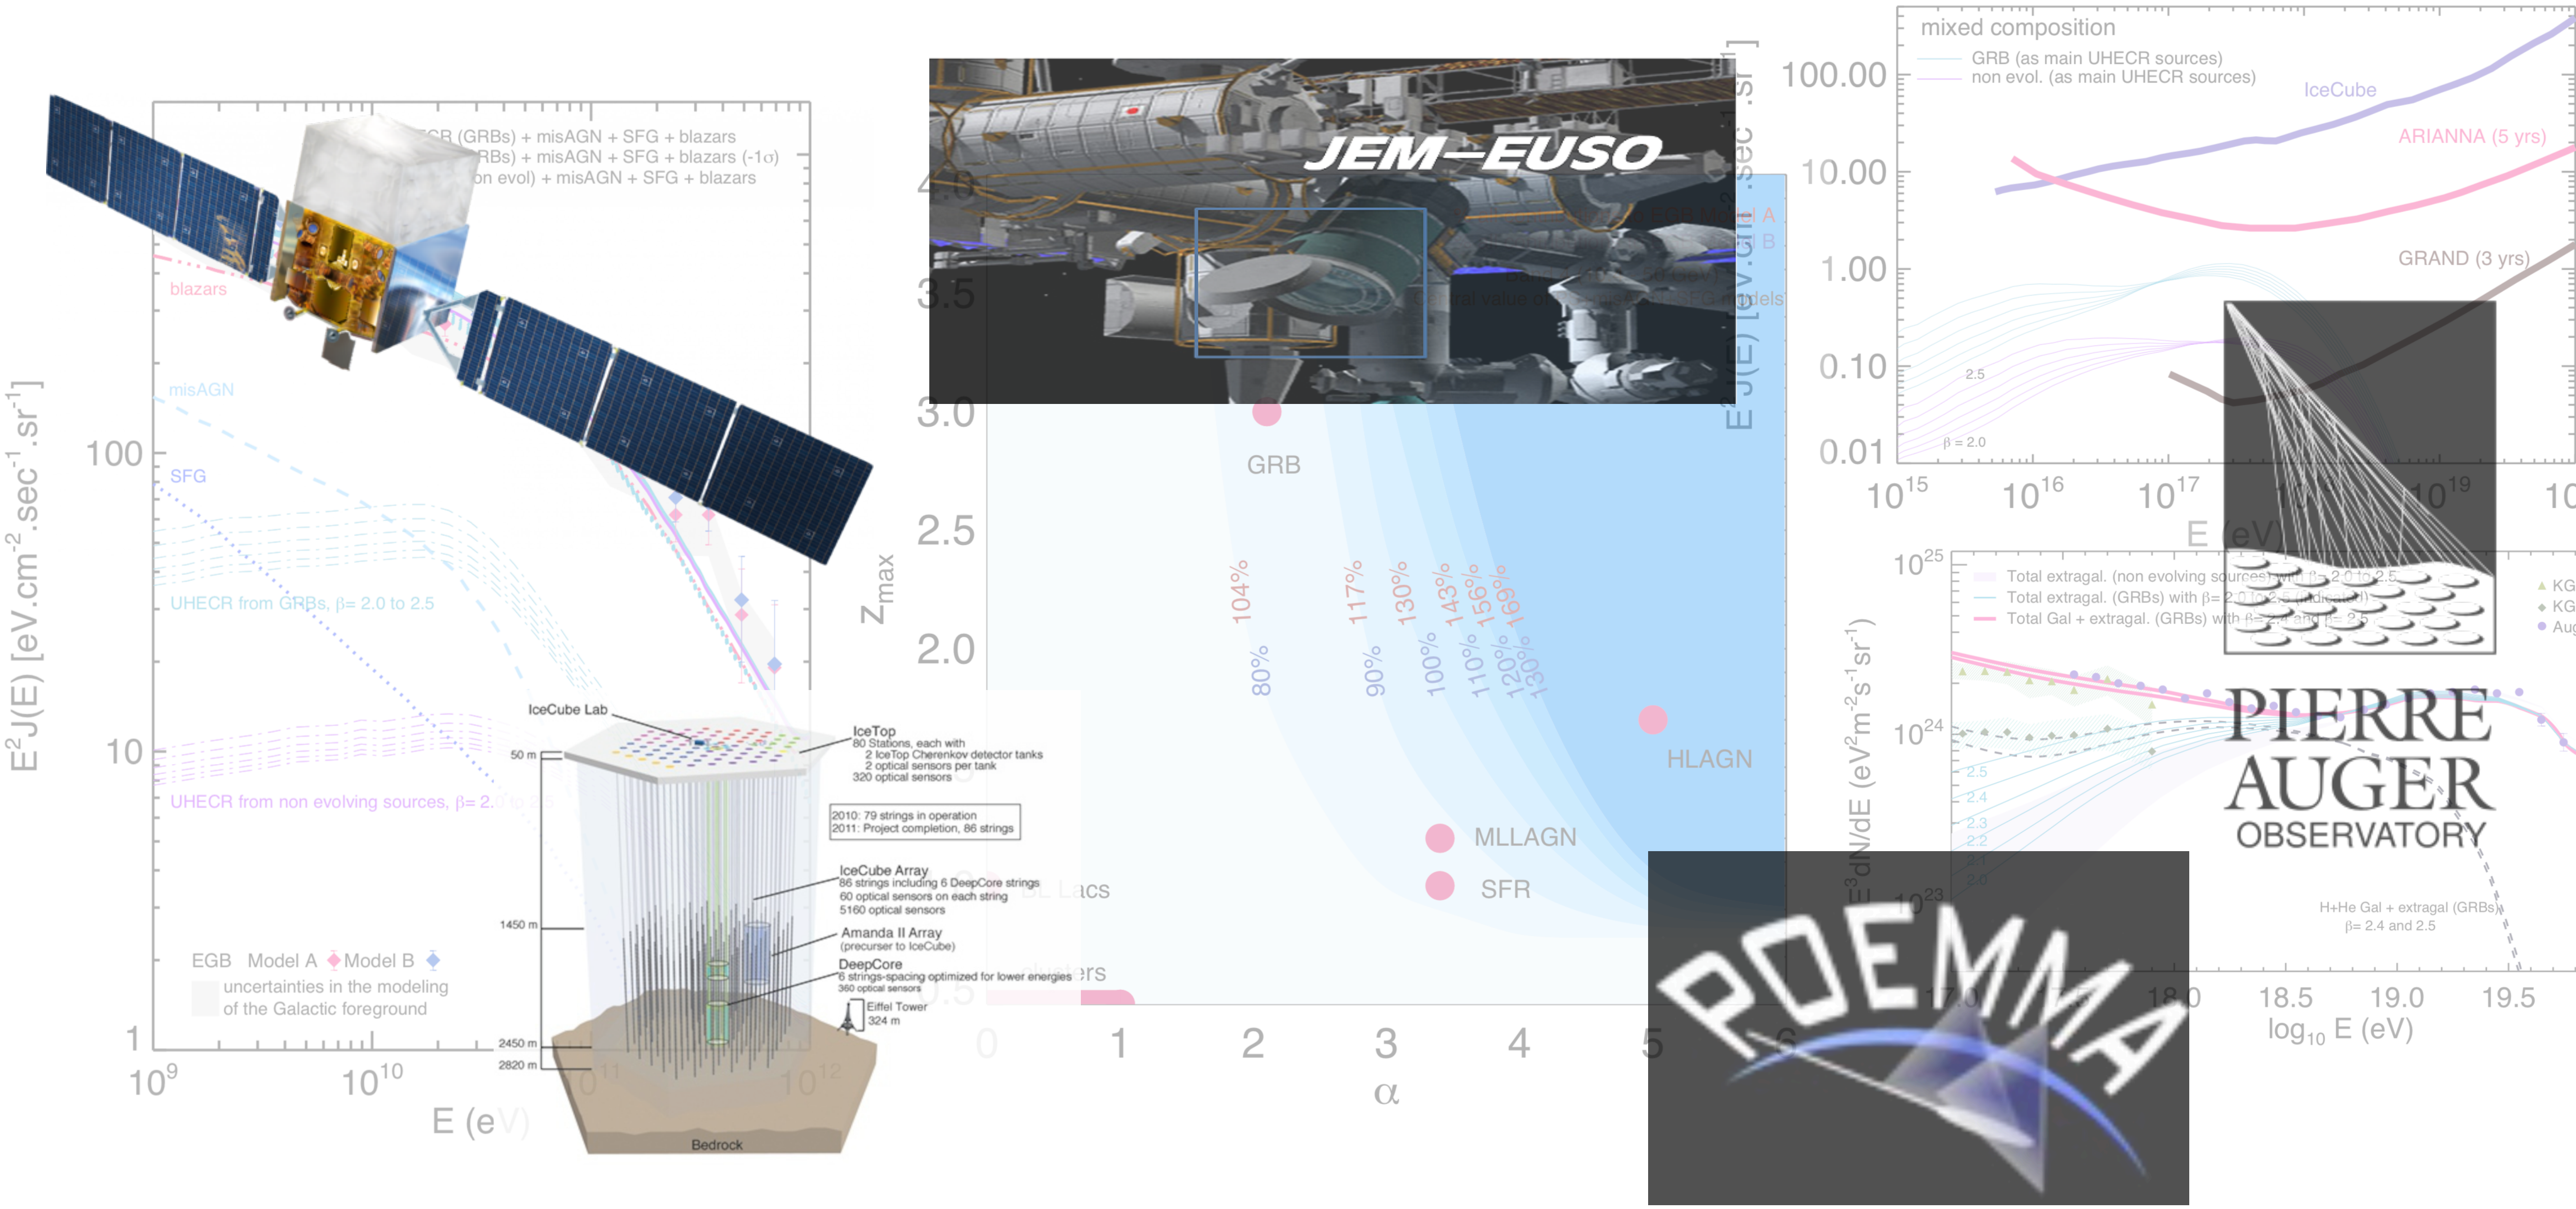
Multimessenger contraints on the origin of ultra-high-energy cosmic-rays



Denis Allard in collaboration with
Noemie Globus, E. Parizot, T. Piran, G.Decerprit, R. Mochkovitch et al.

Ultra-high-energy cosmic-rays (UHECR), neutrinos and photons : the multi-messenger link

UHECR ($E>10^{17}$ eV) are strongly suspected to be of extragalactic origin

Extragalactic ultra-high-energy cosmic-rays must loose energy and produce secondary (cosmogenic) neutrinos and gamma-rays during their propagation interacting with the extragalactic background light (UV-optical-IR, CMB)

- pair production: $N+\gamma \rightarrow N+e^{+}/e^{-}$ $==> secondary\ e^{+/-}$

Threshold with CMB photons ~10^{18} eV per nucleon (at z=0)

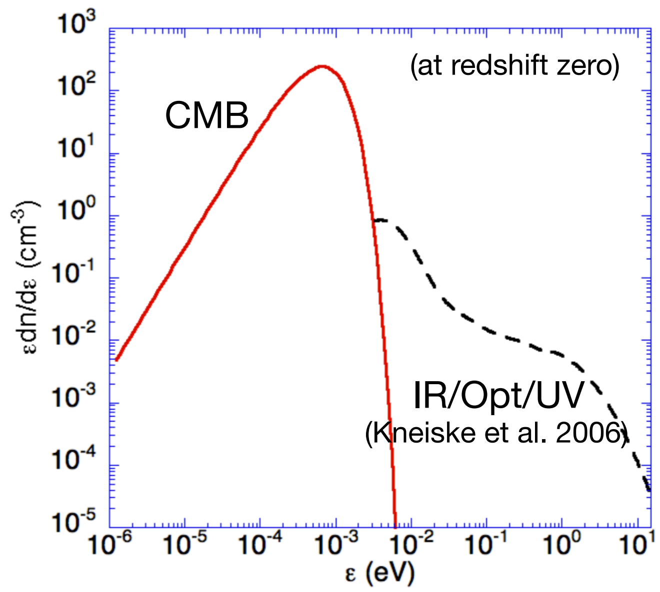
- Pion and meson production :

$\pi^0 \rightarrow 2\gamma$

$\pi^+ \rightarrow \mu^+ + \nu_\mu,\ \mu^+ \rightarrow \overline{\nu_\mu} + e^+ + \nu_e$ $==> secondary\ e^{+/-}, \gamma\ and\ \nu$

$\pi^- \rightarrow \mu^- + \overline{\nu_\mu},\ \mu^- \rightarrow \nu_\mu + e^- + \overline{\nu_e}$

Threshold with CMB photons ~10^{20} eV per nucleon (at z=0)



mechanism responsible for the GZK cut-off at least for UHECR protons

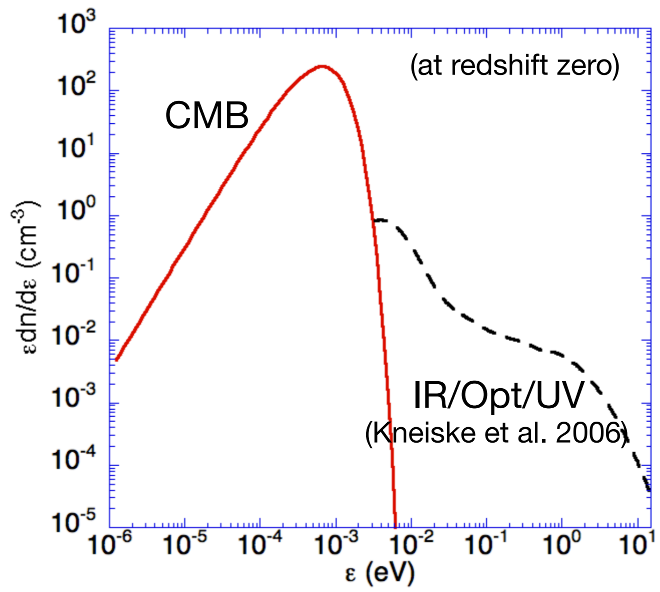
Ultra-high-energy cosmic-rays (UHECR), neutrinos and photons : the multi-messenger link

UHECR ($E>10^{17}$ eV) are strongly suspected to be of extragalactic origin

Extragalactic ultra-high-energy cosmic-rays must loose energy and produce secondary (cosmogenic) neutrinos and gamma-rays during their propagation interacting with the extragalactic background light (UV-optical-IR, CMB)

- pair production: $N+\gamma \rightarrow N+e^+/e^-$ $==> secondary\ e^{+/-}$
- Pion and meson production :

$$\pi^0 \rightarrow 2\gamma$$
$$\pi^+ \rightarrow \mu^+ + \nu_\mu,\ \mu^+ \rightarrow \overline{\nu_\mu} + e^+ + \nu_e ==> secondary\ e^{+/-}, \gamma\ and\ \nu$$
$$\pi^- \rightarrow \mu^- + \overline{\nu_\mu},\ \mu^- \rightarrow \nu_\mu + e^- + \overline{\nu_e}$$



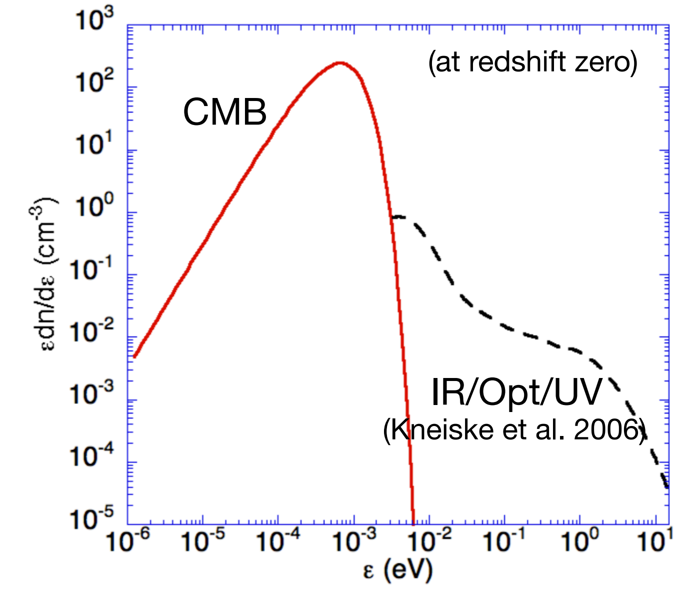
νs do not interact while propagating in the extragalactic medium
while the universe is opaque to VHE e^+/e^- and γ which cascade down to sub-TeV energies

Diffuse UHECR ($E>10^{17}$ eV) flux
➡ diffuse ν flux in the PeV-EeV range
➡ diffuse γ-ray flux in the GeV-TeV range

Ultra-high-energy cosmic-rays (UHECR), neutrinos and photons : the multi-messenger link

UHECR (E>10[17] eV) are strongly suspected to be of extragalactic origin

Extragalactic ultra-high-energy cosmic-rays must loose energy and produce secondary (cosmogenic) neutrinos and gamma-rays during their propagation interacting with the extragalactic background light (UV-optical-IR, CMB)

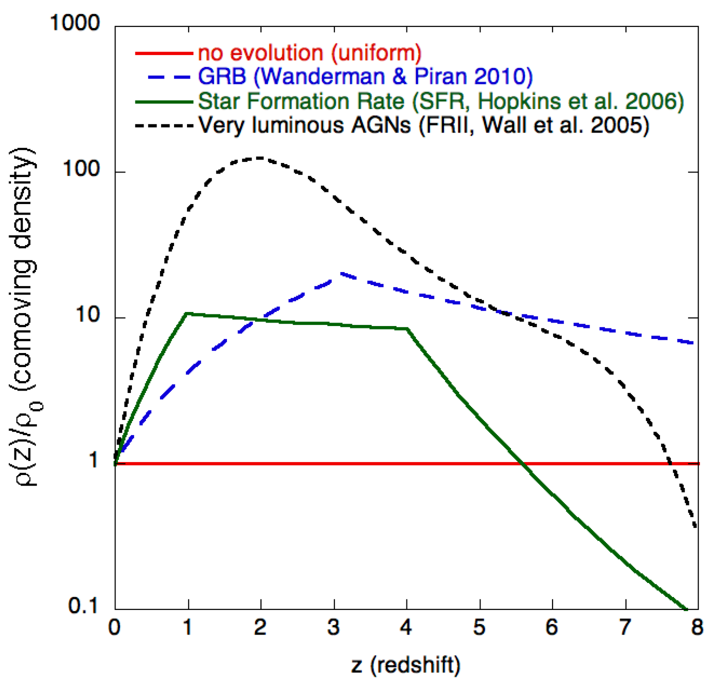


- pair production: N+γ→N+e⁺/e⁻ $==> secondary\ e^{+/-}$
- Pion and meson production :

$$\pi^0 \to 2\gamma$$
$$\pi^+ \to \mu^+ + \nu_\mu,\ \mu^+ \to \overline{\nu_\mu} + e^+ + \nu_e ==> secondary\ e^{+/-}, \gamma\ and\ \nu$$
$$\pi^- \to \mu^- + \overline{\nu_\mu},\ \mu^- \to \nu_\mu + e^- + \overline{\nu_e}$$

The extragalactic photon backgrounds evolve with time, they are hotter and denser as the redshift increases

➡ cosmological evolution of the sources is expected to have a strong impact on cosmogenic photons and neutrino fluxes



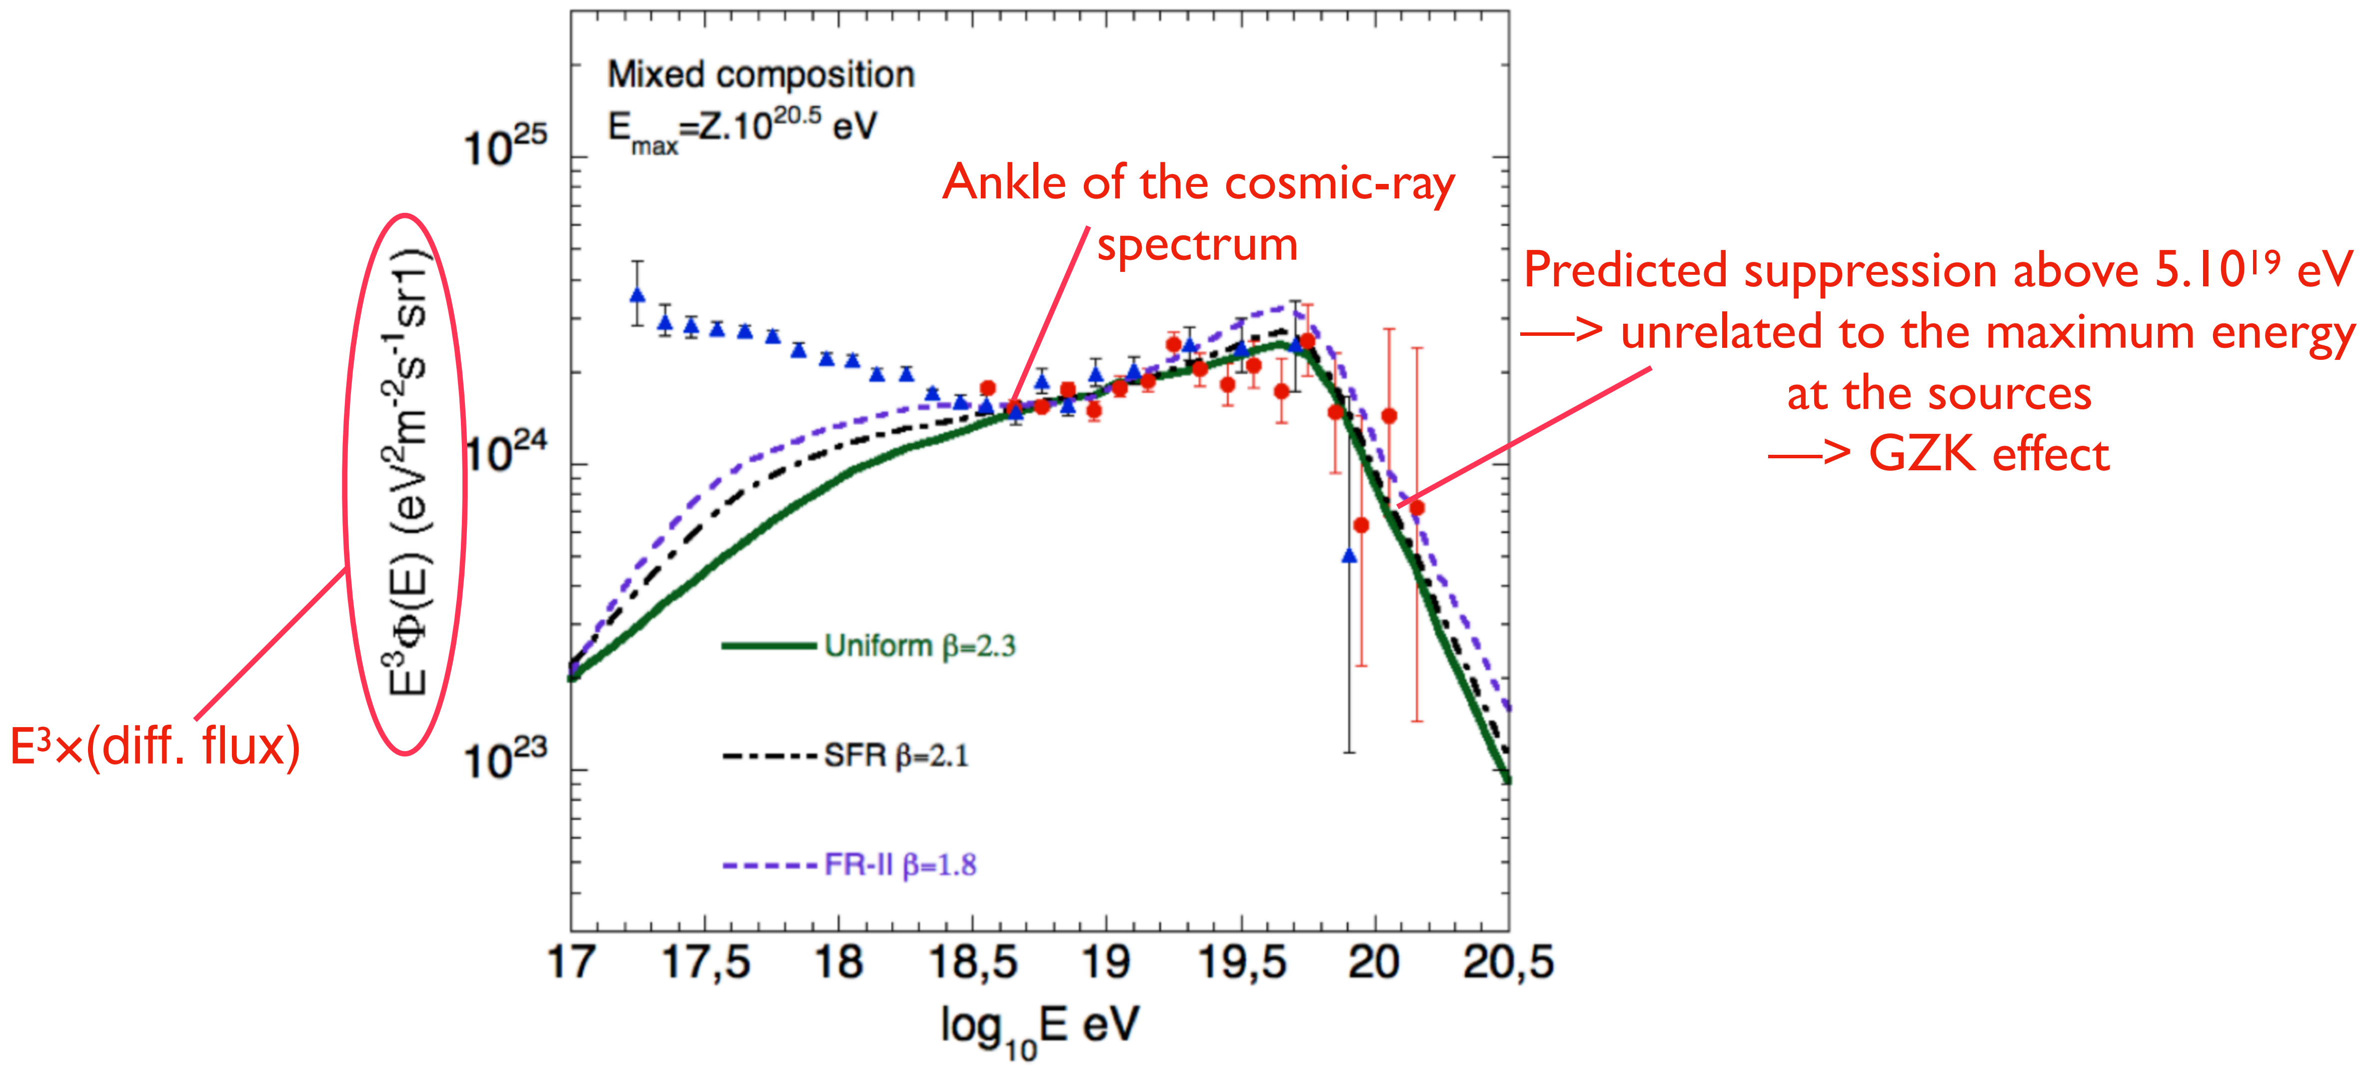
4 different hypotheses on the source evolution in the following :

- A very strong evolution such as that of very luminous AGNs (hereafter labeled FR-II)
- 2 "intermediate" evolutions following the "star formation rate" (SFR) and the evolution of GRB sources
- A baseline case with no evolution (often labeled "uniform")

One example : mixed composition assumed at UHECR sources

Assuming the maximum energy per nucleon is above 10^{20} eV (what most people thought until ~2010) mixed composition similar to that of low energy galactic cosmic-rays :

$N(E) \propto E^{-\beta}$, $E_{max}(Z)=Z\times E_{max}^{proton}$, $E_{max}^{proton}=10^{20.5}$ eV

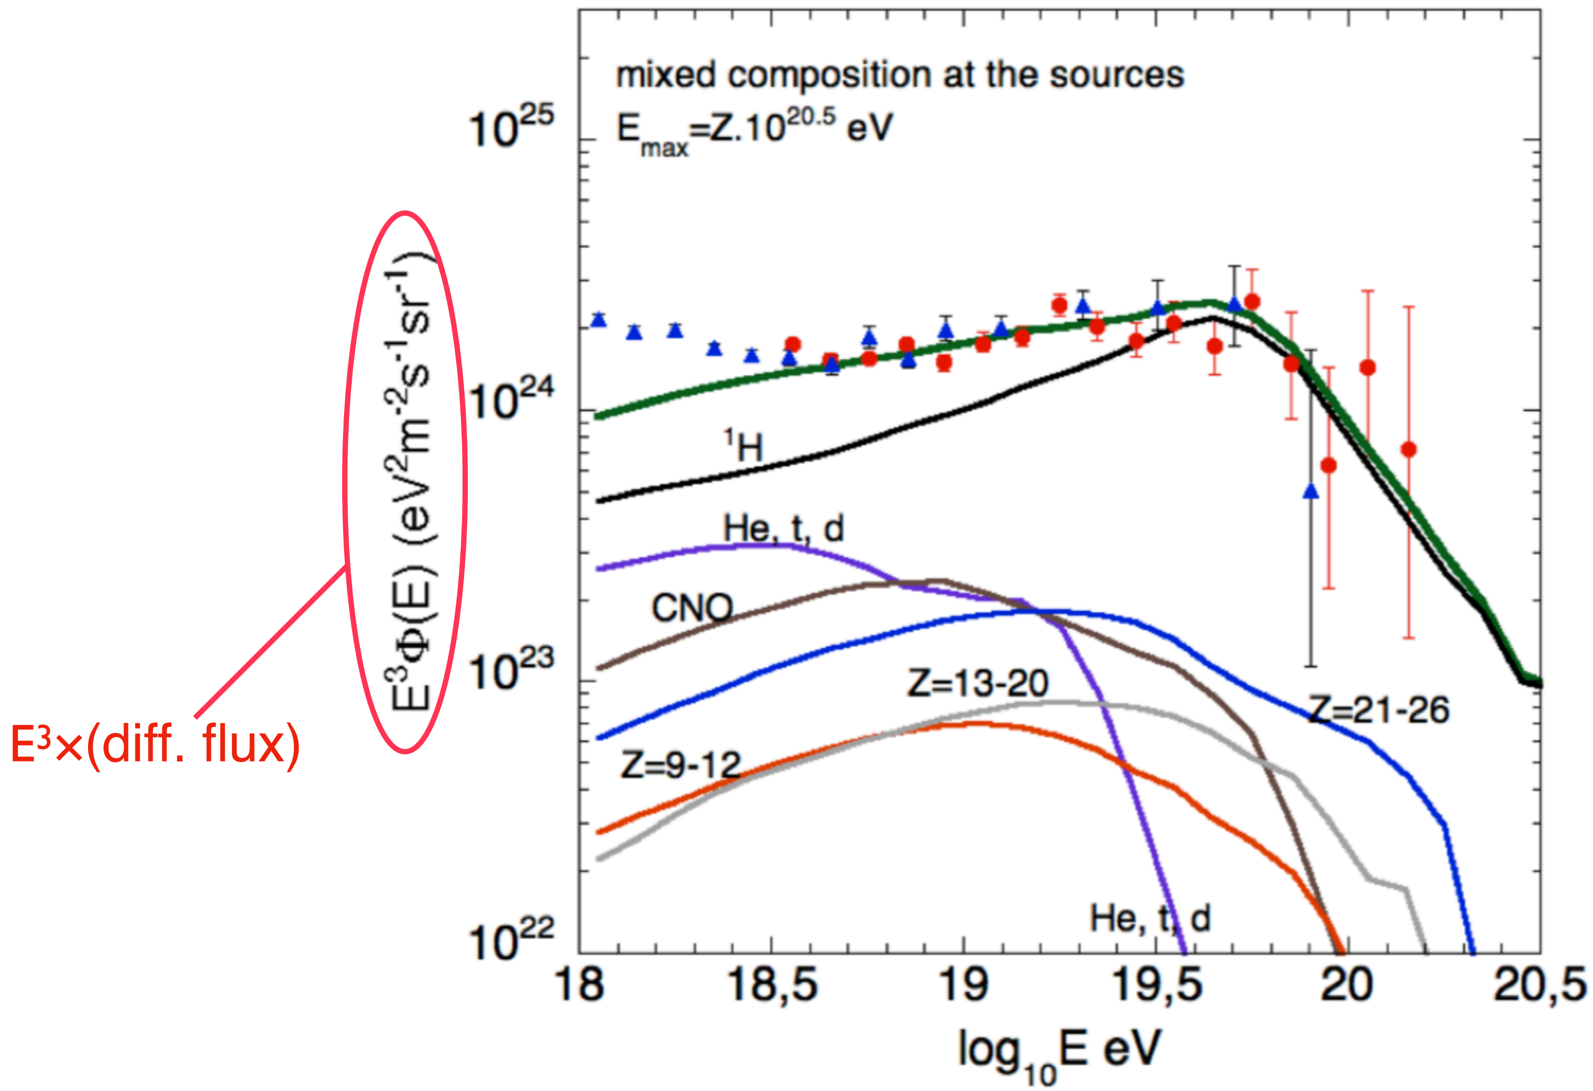


The UHECR spectrum can be well reproduced above the ankle
—> the ankle is interpreted in this case as a signature of the transition between Galactic and extragalactic cosmic-rays (more precisely the end of the transition)

One example : mixed composition assumed at UHECR sources

Assuming the maximum energy per nucleon is above 10^{20} eV (what most people thought until ~2010) mixed composition similar to that of low energy galactic cosmic-rays :

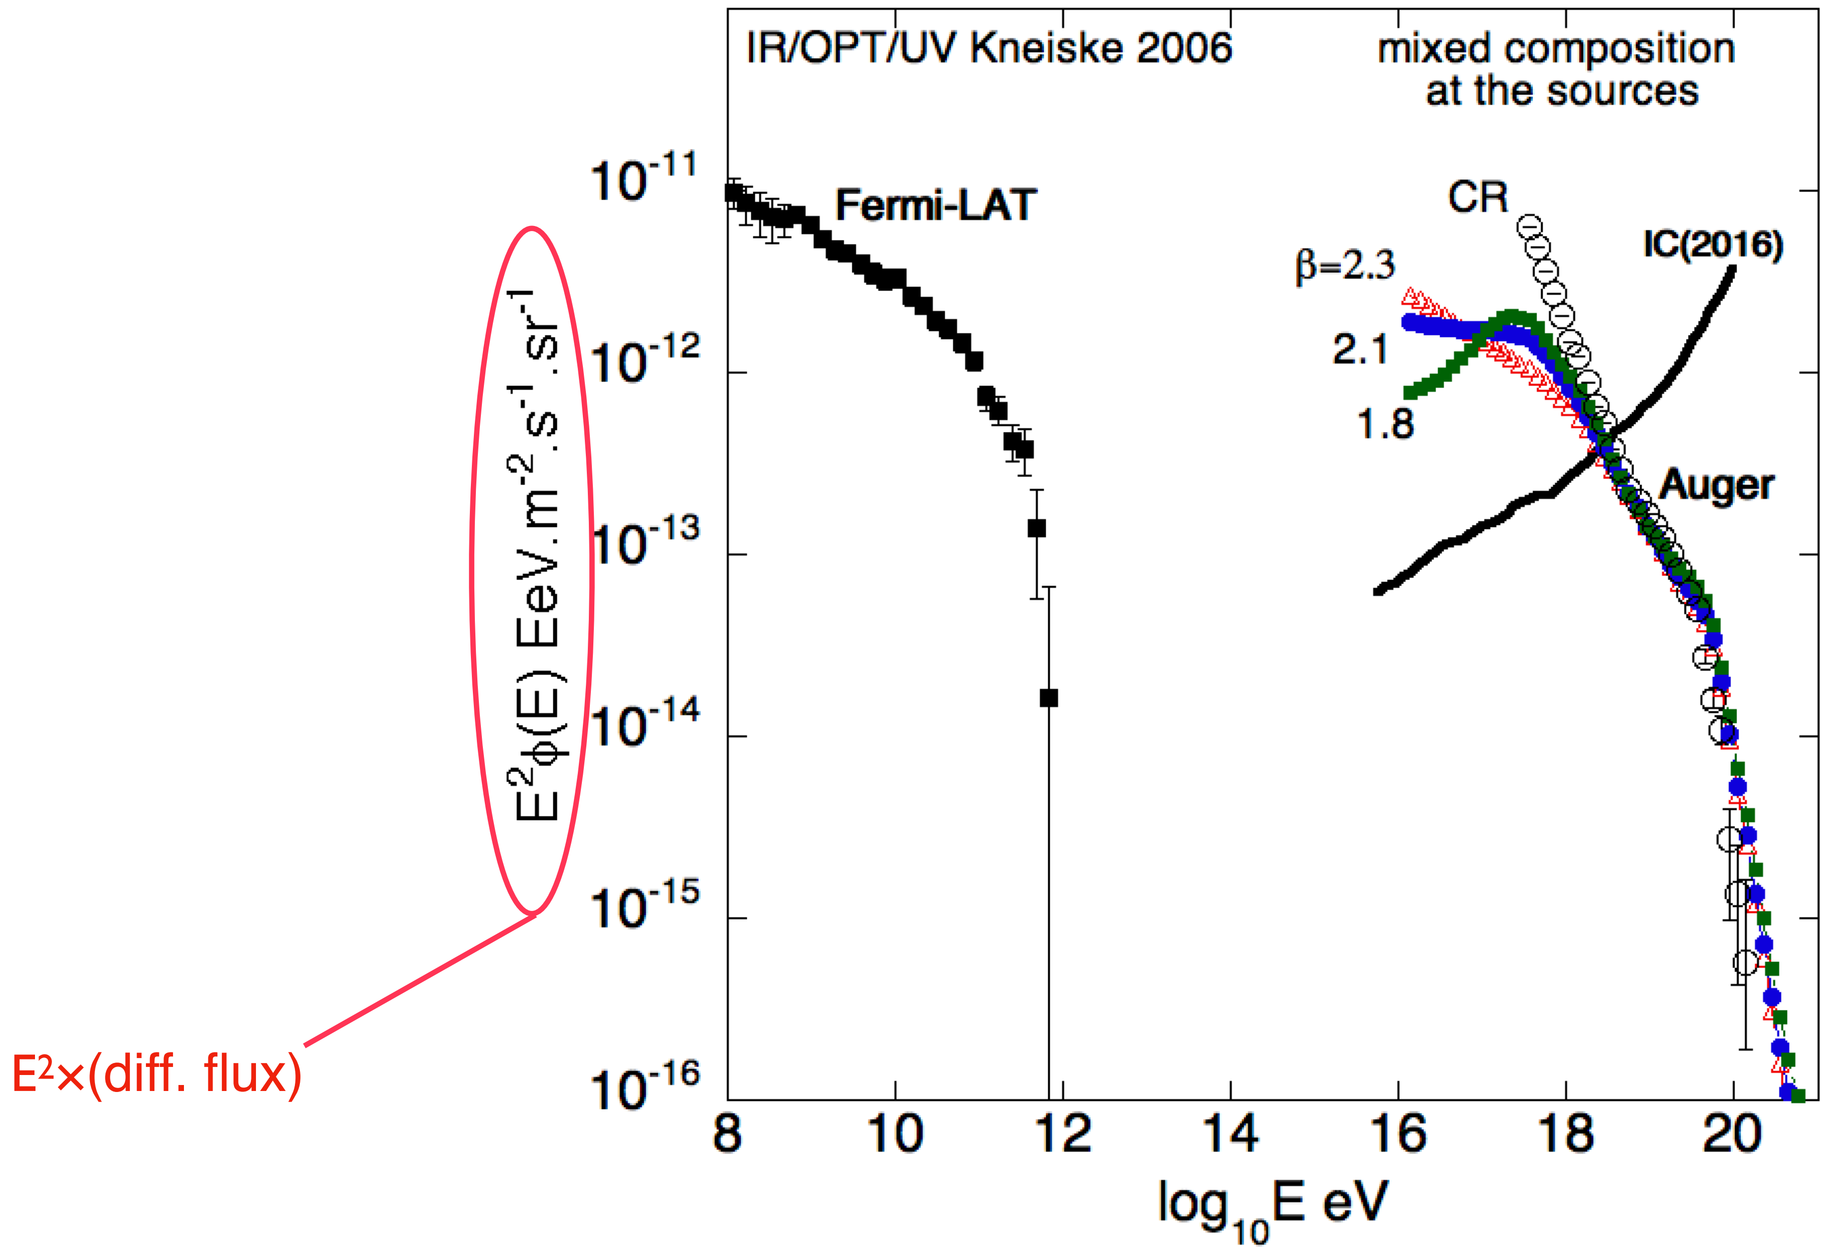
$N(E) \propto E^{-\beta}$, $E_{max}(Z)=Z\times E_{max}^{proton}$, $E_{max}^{proton}=10^{20.5}$ eV



When all the species are assumed to be accelerated above 10^{20} eV, the composition is expected to get lighter (i.e proton richer) above 10^{19} eV (photodisintegration of composed species)

One example : mixed composition assumed at UHECR sources

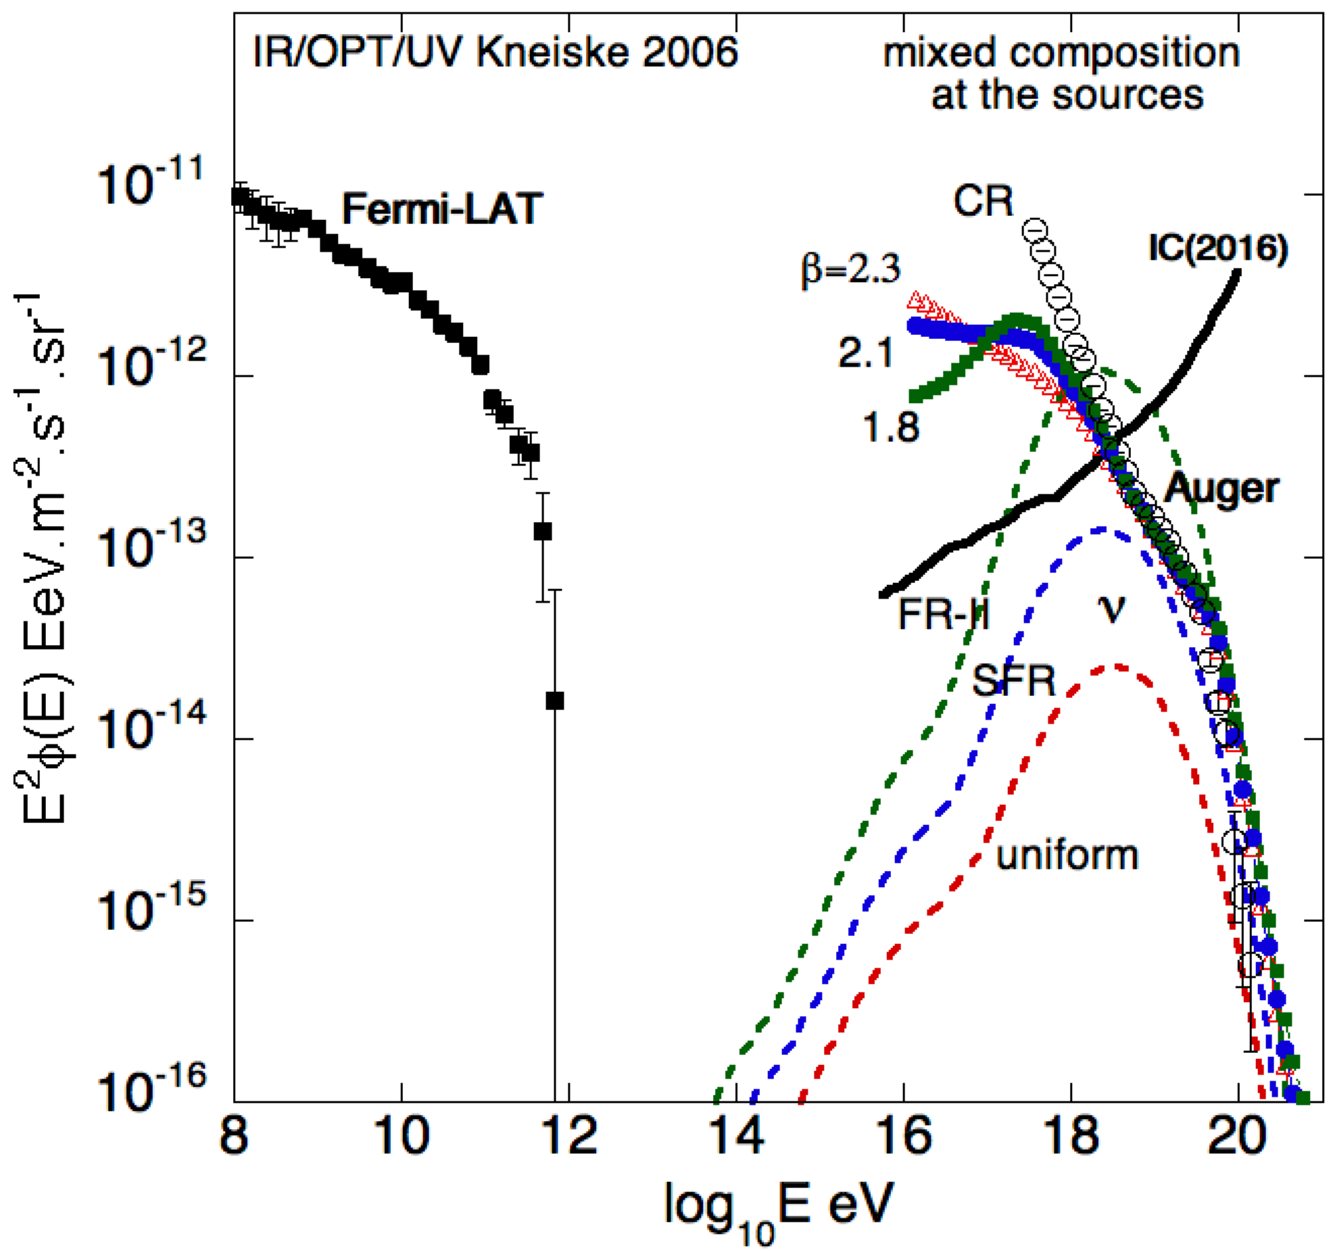
Aartsen et al. 2016, Phys. Rev. Lett. 117 (24)
Ackermann et al. 2015, ApJ 799:86
Auger Collaboration 2015 (ICRC)



One example : mixed composition assumed at UHECR sources

Aartsen et al. 2016, Phys. Rev. Lett. 117 (24)
Ackermann et al. 2015, ApJ 799:86
Auger Collaboration 2015 (ICRC)

Neutrino "bumps" peaking around 10^{18} eV —> produced by UHECR >>10^{19} eV per nucleon —> π-photoproduction on CMB photons



Strong impact of the cosmological evolution of the sources on the cosmogenic ν fluxes —> evolutions significantly stronger than SFR constrained by IceCube

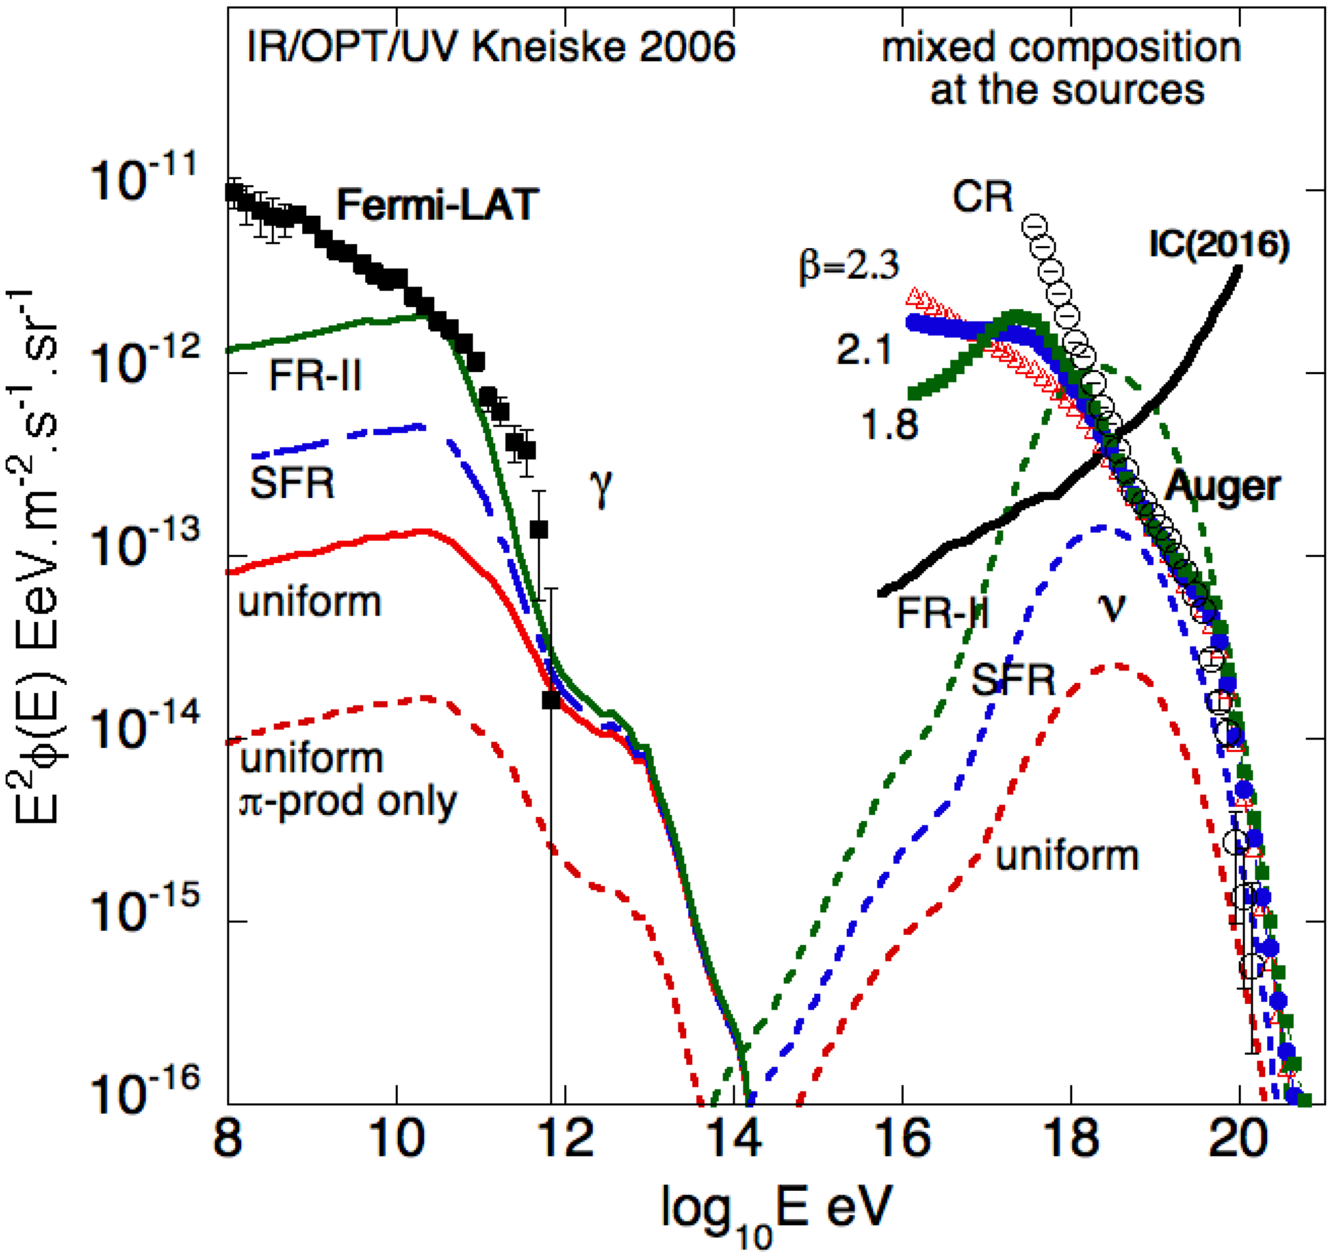
One example : mixed composition assumed at UHECR sources

Aartsen et al. 2016, Phys. Rev. Lett. 117 (24)
Ackermann et al. 2015, ApJ 799:86
Auger Collaboration 2015 (ICRC)

All the energy released in γ and e^+e^- piles up in the subTeV range

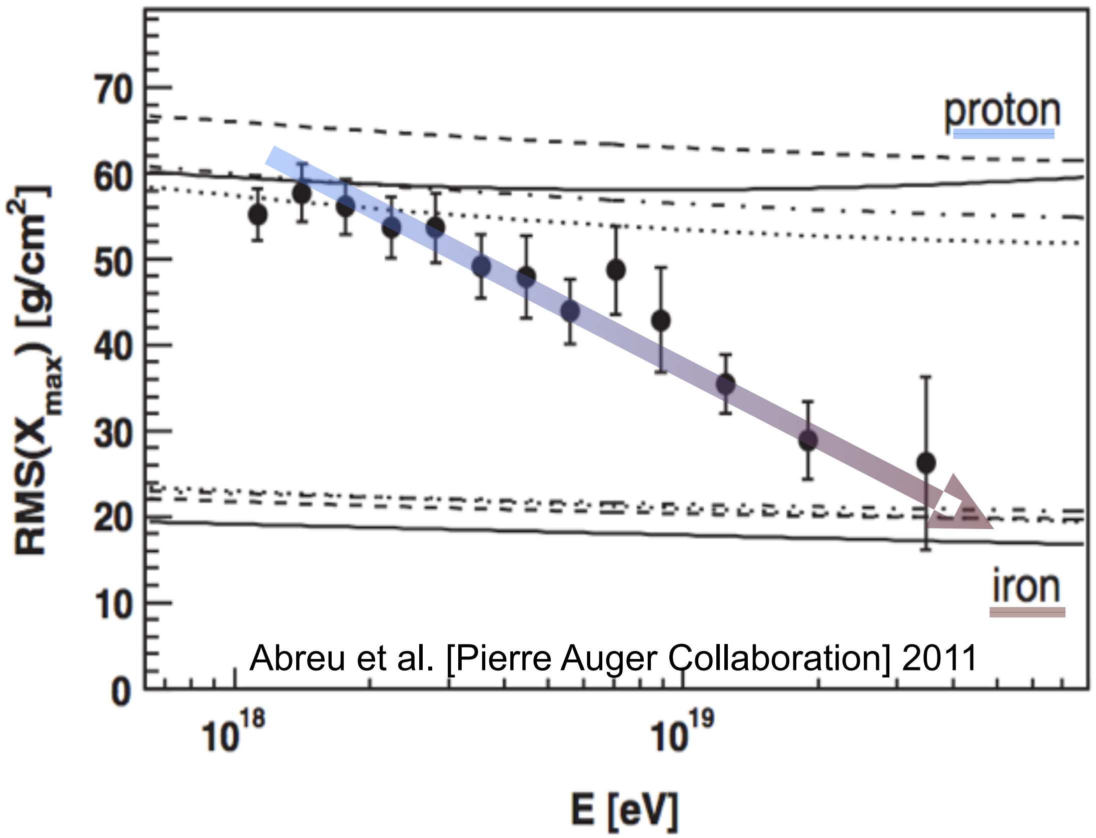
Strong impact of the cosmological evolution of the sources on the cosmogenic γ fluxes —> strongest evolution also ruled out by Fermi-LAT IGRB

(Adapted from Decerprit and Allard, A&A, 2011)



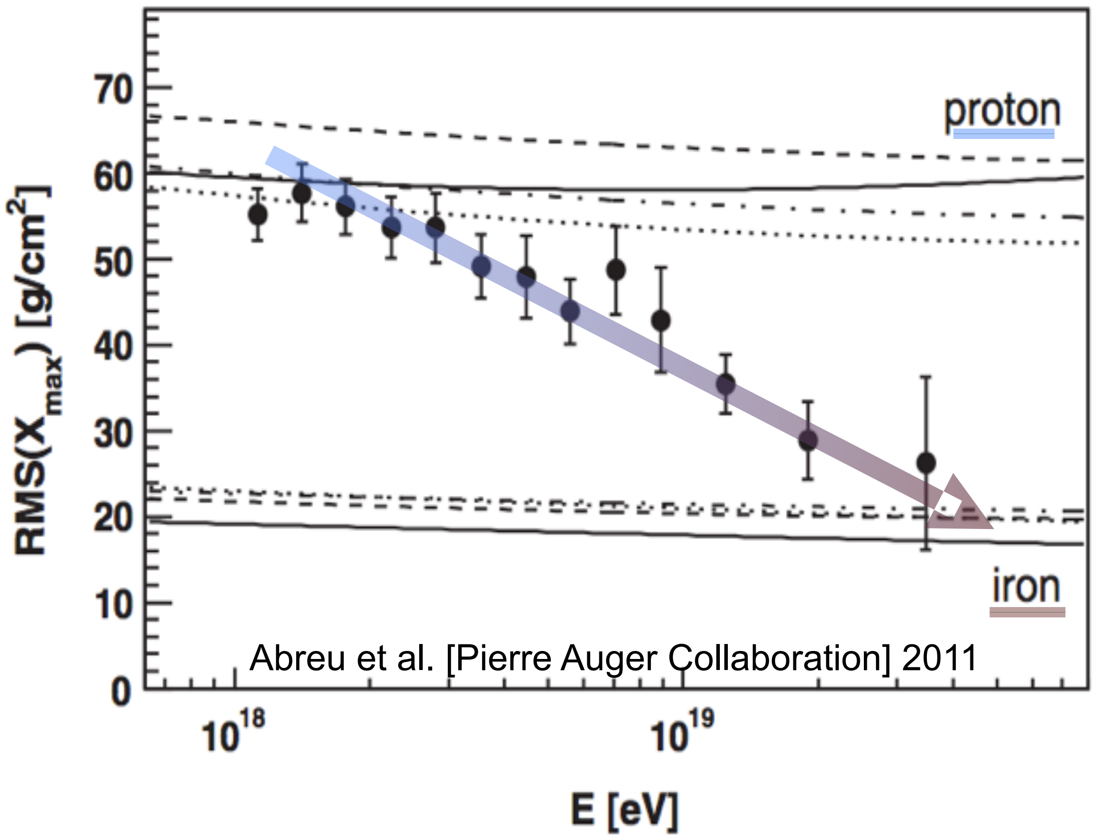
subdominant contribution of π-photoproduction to cosmogenic γs —> dominant contribution of the e^+e^- pair production —> unlike cosmogenic νs, cosmogenic γs are not produced by the highest energy particles

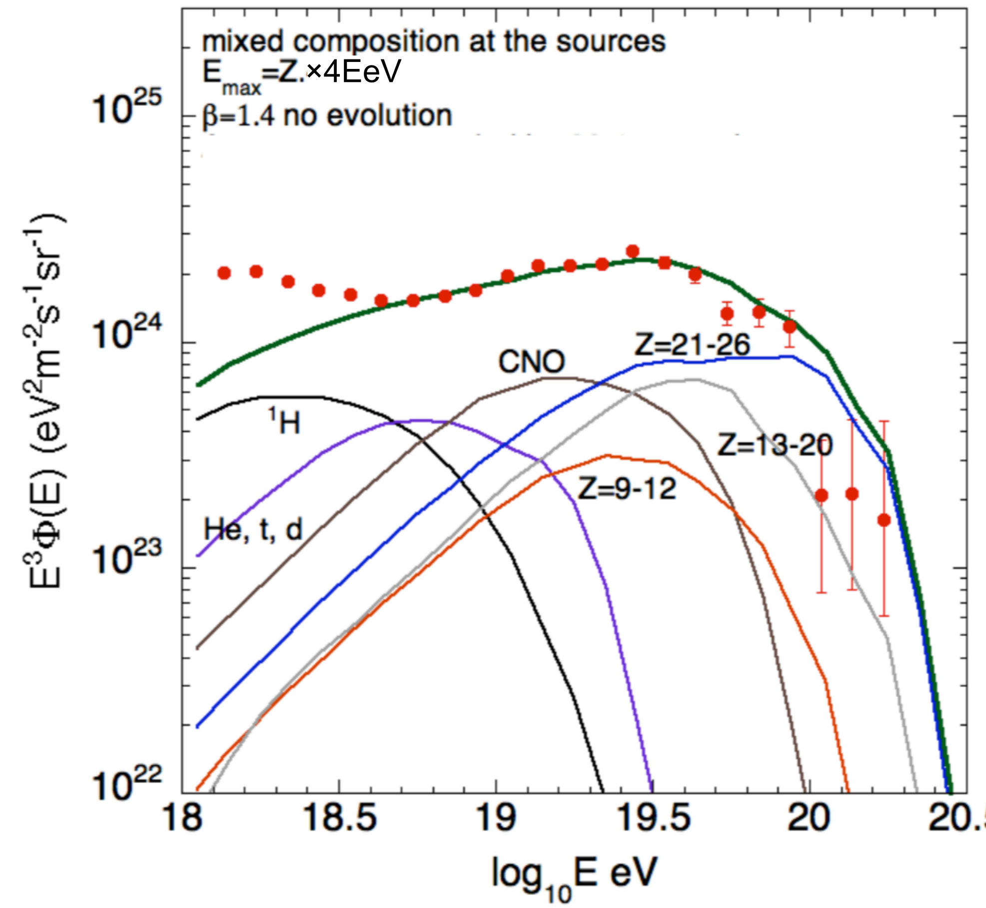
Implications of Auger composition measurements



The evolution of the composition implied by Auger composition analyses strongly suggest that the composition is becoming heavier as the energy increases

Implications of Auger composition measurements





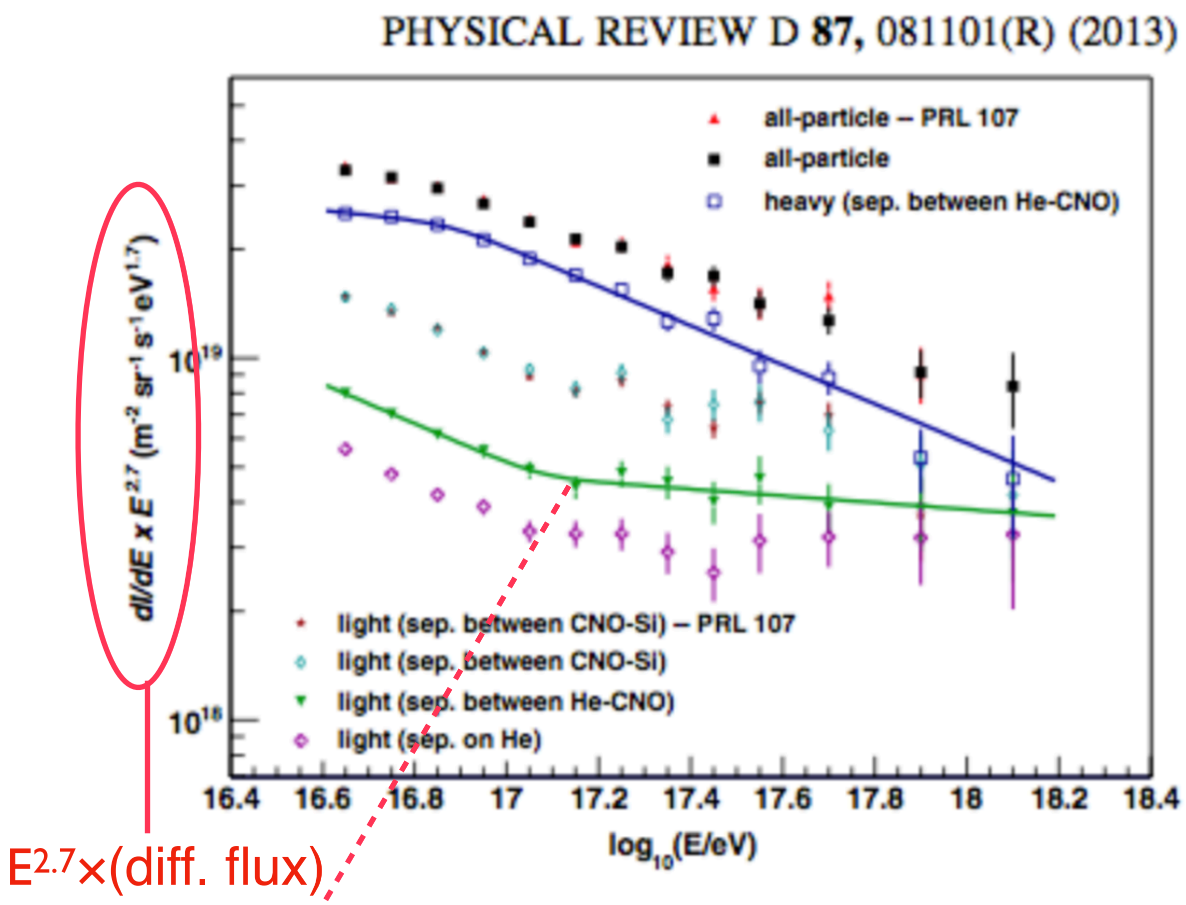
The evolution of the composition implied by Auger composition analyses strongly suggest that the composition is becoming heavier as the energy increases
—> dominant sources of UHECR do not accelerate protons to the highest energies

Low maximum energy per nucleon (a few EeV to 10^{19} eV, well below the pion production threshold with CMB photons) and hard source spectral indexes required

here $N(E) \propto E^{-\beta}$, $\beta=1.4$, $E_{max}(Z)=Z\times E_{max}^{proton}$, $E_{max}^{proton}=4.10^{18}$ eV

obviously not a good news for UHE cosmogenic neutrinos predictions

KASCADE-Grande's light ankle



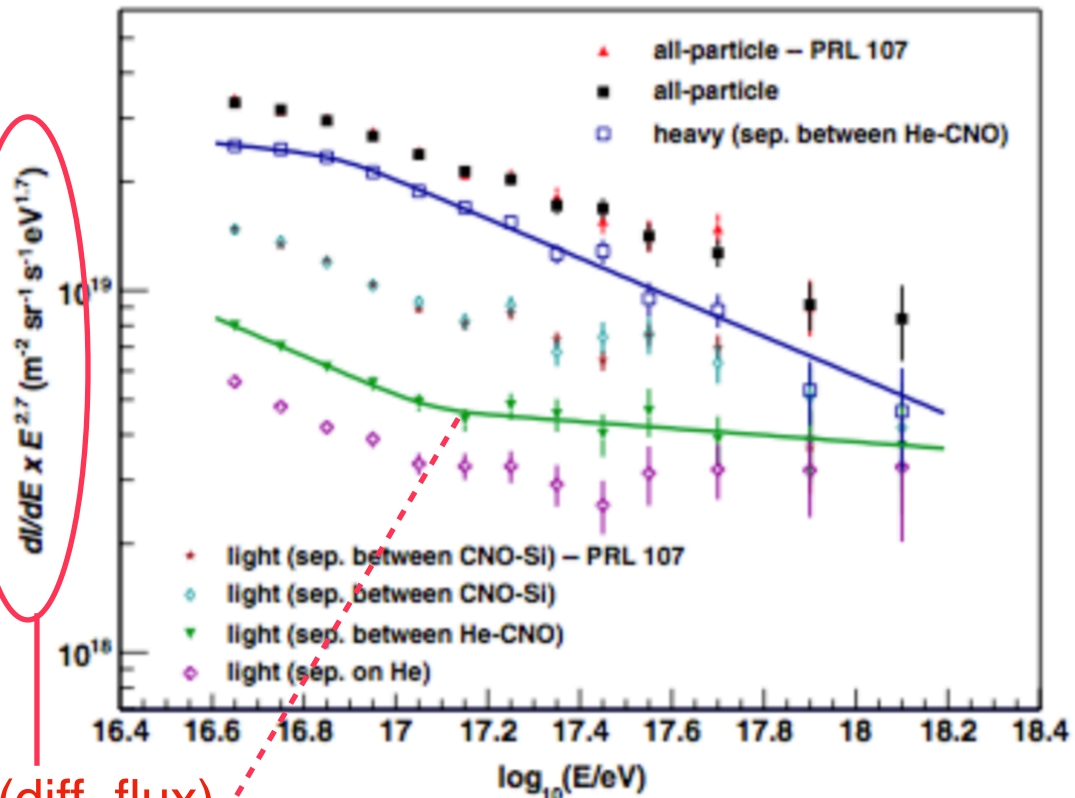
KASCADE-Grande's light ankle, equivalent to the ankle of the cosmic-ray spectrum but for the light component (H-He), around 10^{17} eV

—> most probably implies that extragalactic light component starts to be significant already at 10^{17} eV

—> light component quite soft above 10^{17} eV (~2.7)

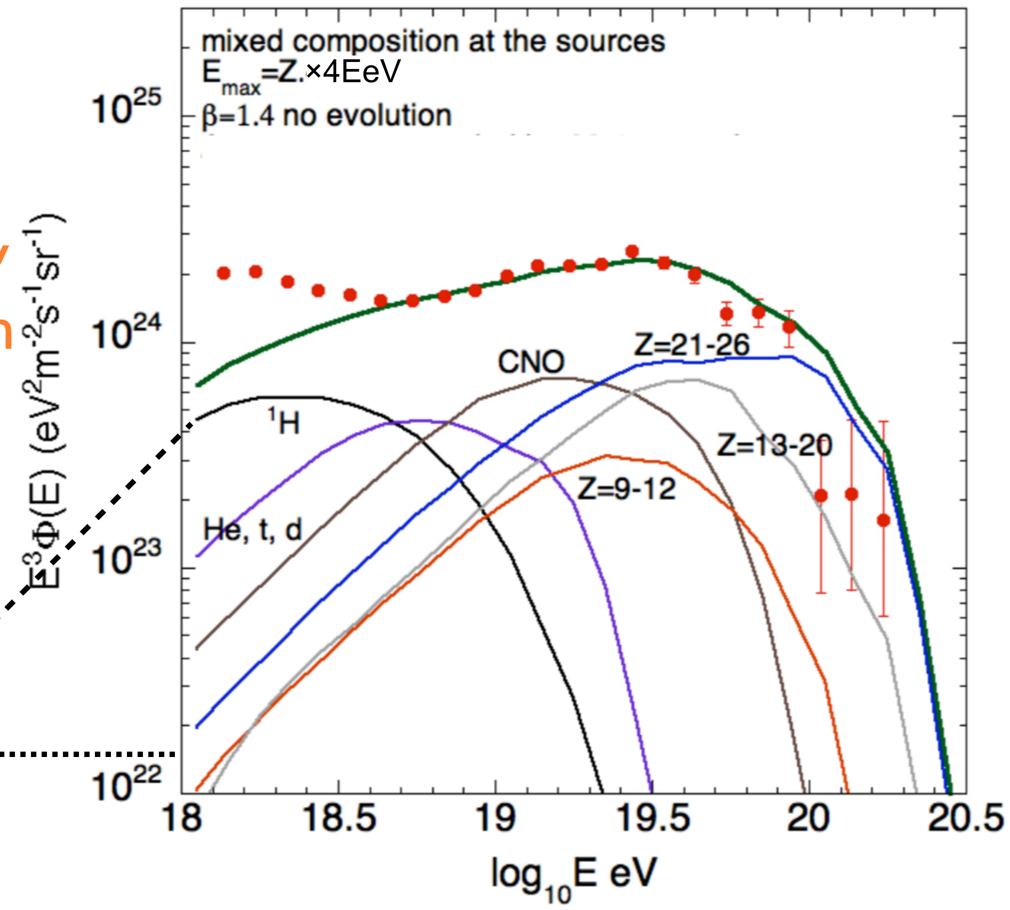
KASCADE-Grande's light ankle

PHYSICAL REVIEW D **87**, 081101(R) (2013)



$E^{2.7}\times$(diff. flux)

significantly harder than E^{-2}



KASCADE-Grande's light ankle, equivalent to the ankle of the cosmic-ray spectrum but for the light component (H-He), around 10^{17} eV

—> most probably implies that extragalactic light component starts to be significant already at 10^{17} eV

—> light component quite soft above 10^{17} eV (~2.7)

Difficult to make a consistent picture of the Auger composition + the light ankle with the above phenomenological model

One would need a much softer spectrum for the light nuclei

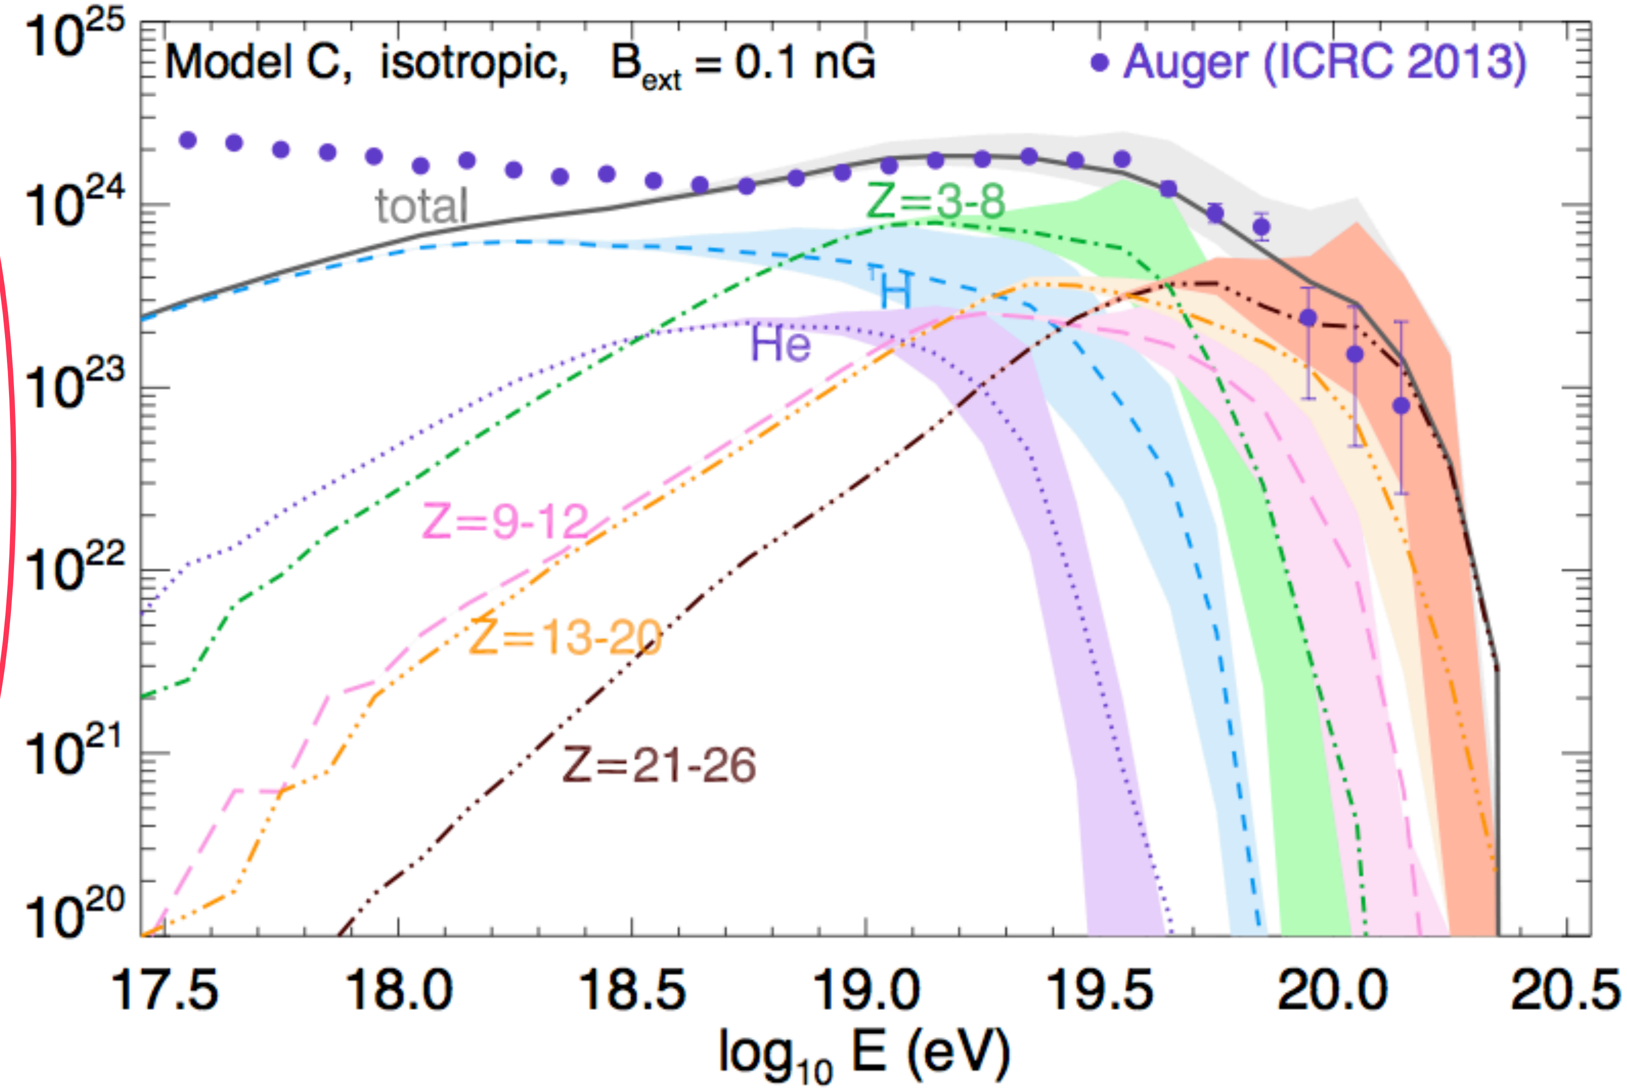
Phenomenological model of UHECR acceleration as a solution to the soft proton spectrum issue

Model of UHECR acceleration at GRB internal shocks (Globus et al. 2015) can reproduce UHECR data (Auger spectrum and composition)

- if most of the energy dissipated is communicated to accelerated cosmic-rays
- the composition injected at the shock has ~ 10 times galactic CR metallicity

NB : Spectrum on earth, sum of the contributions of all GRB after propagation in the extragalactic medium

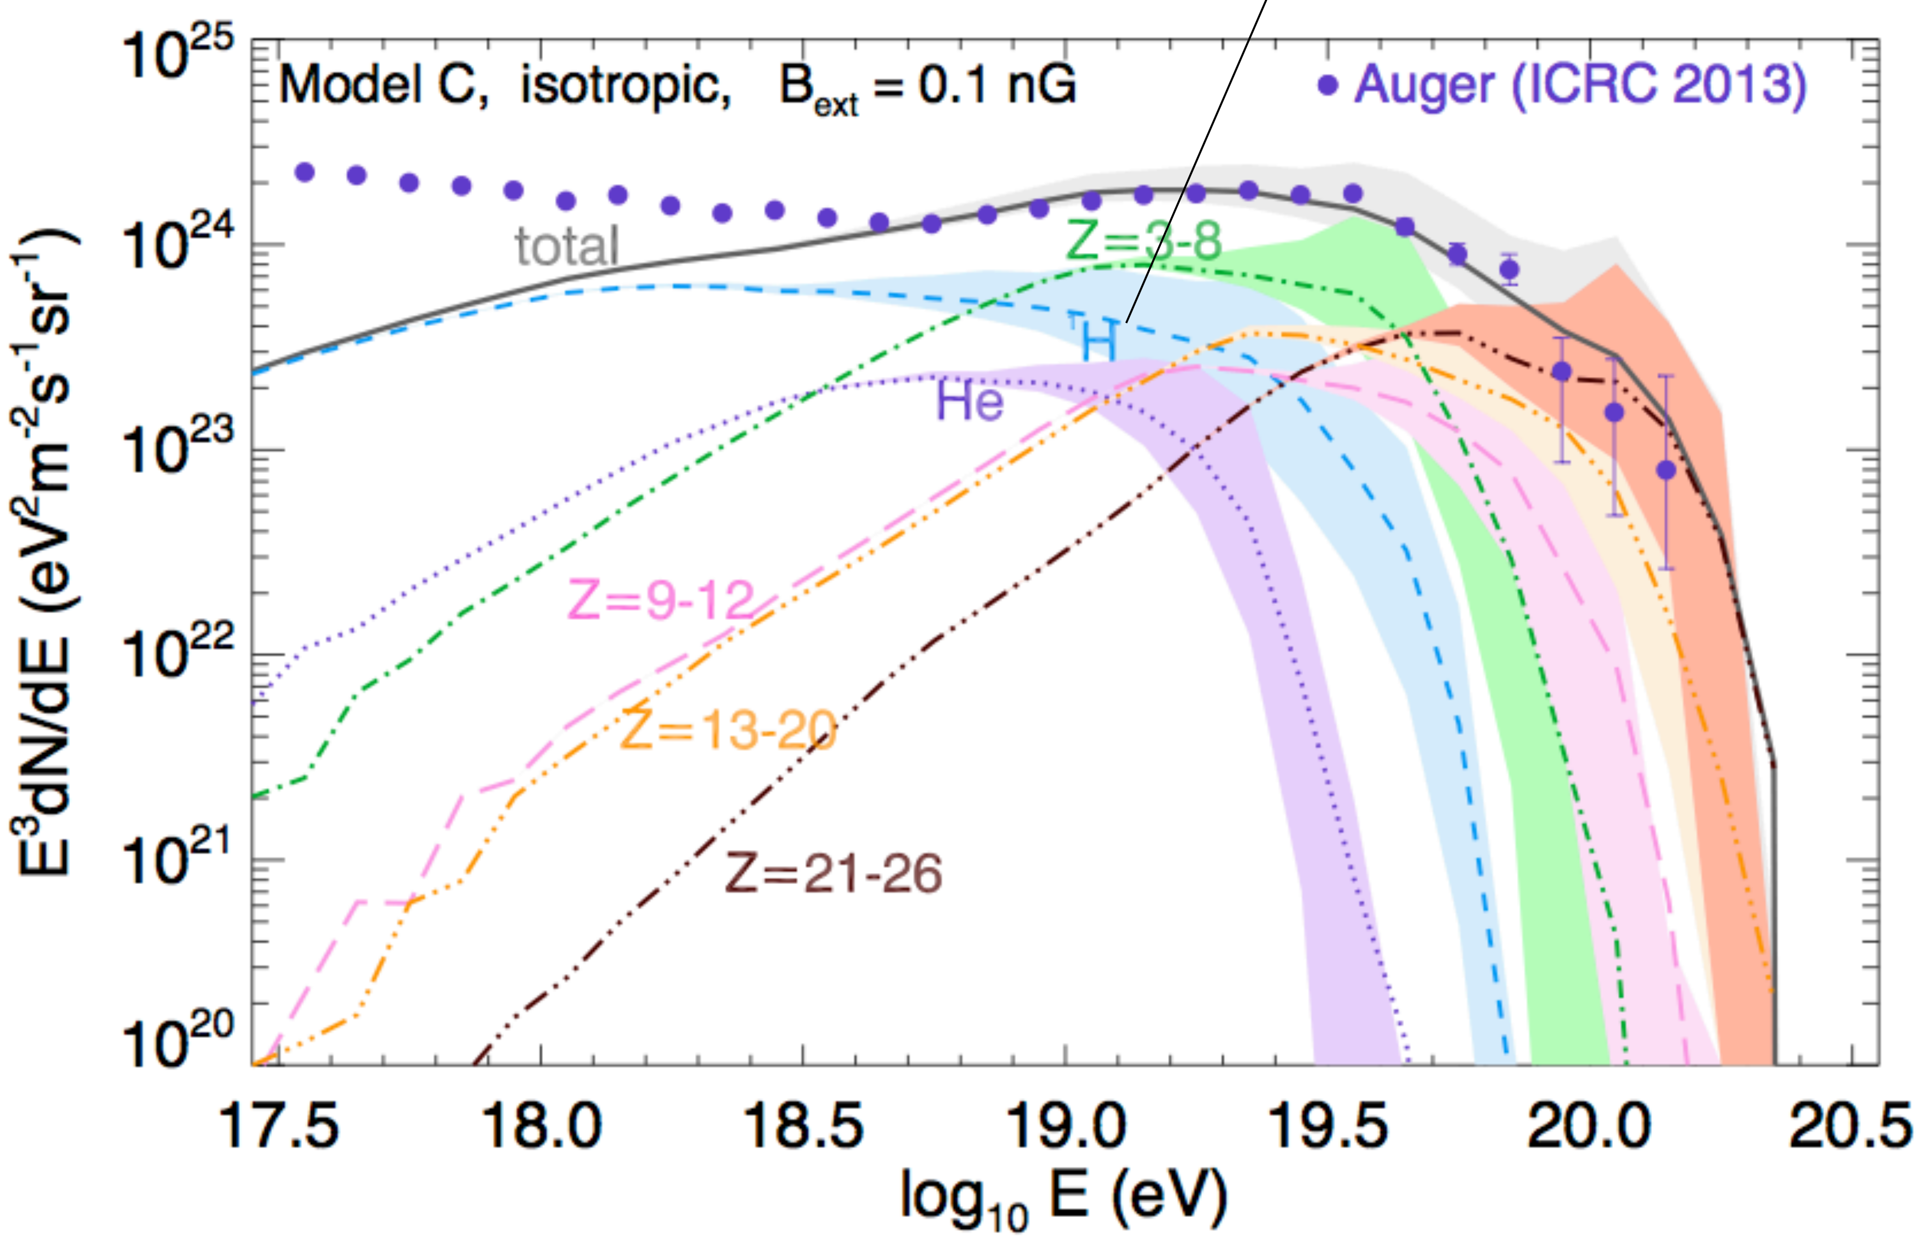
$E^3\times$(diff. flux)



N. Globus, D. Allard, R. Mochkovitch, E. Parizot, MNRAS, 2015

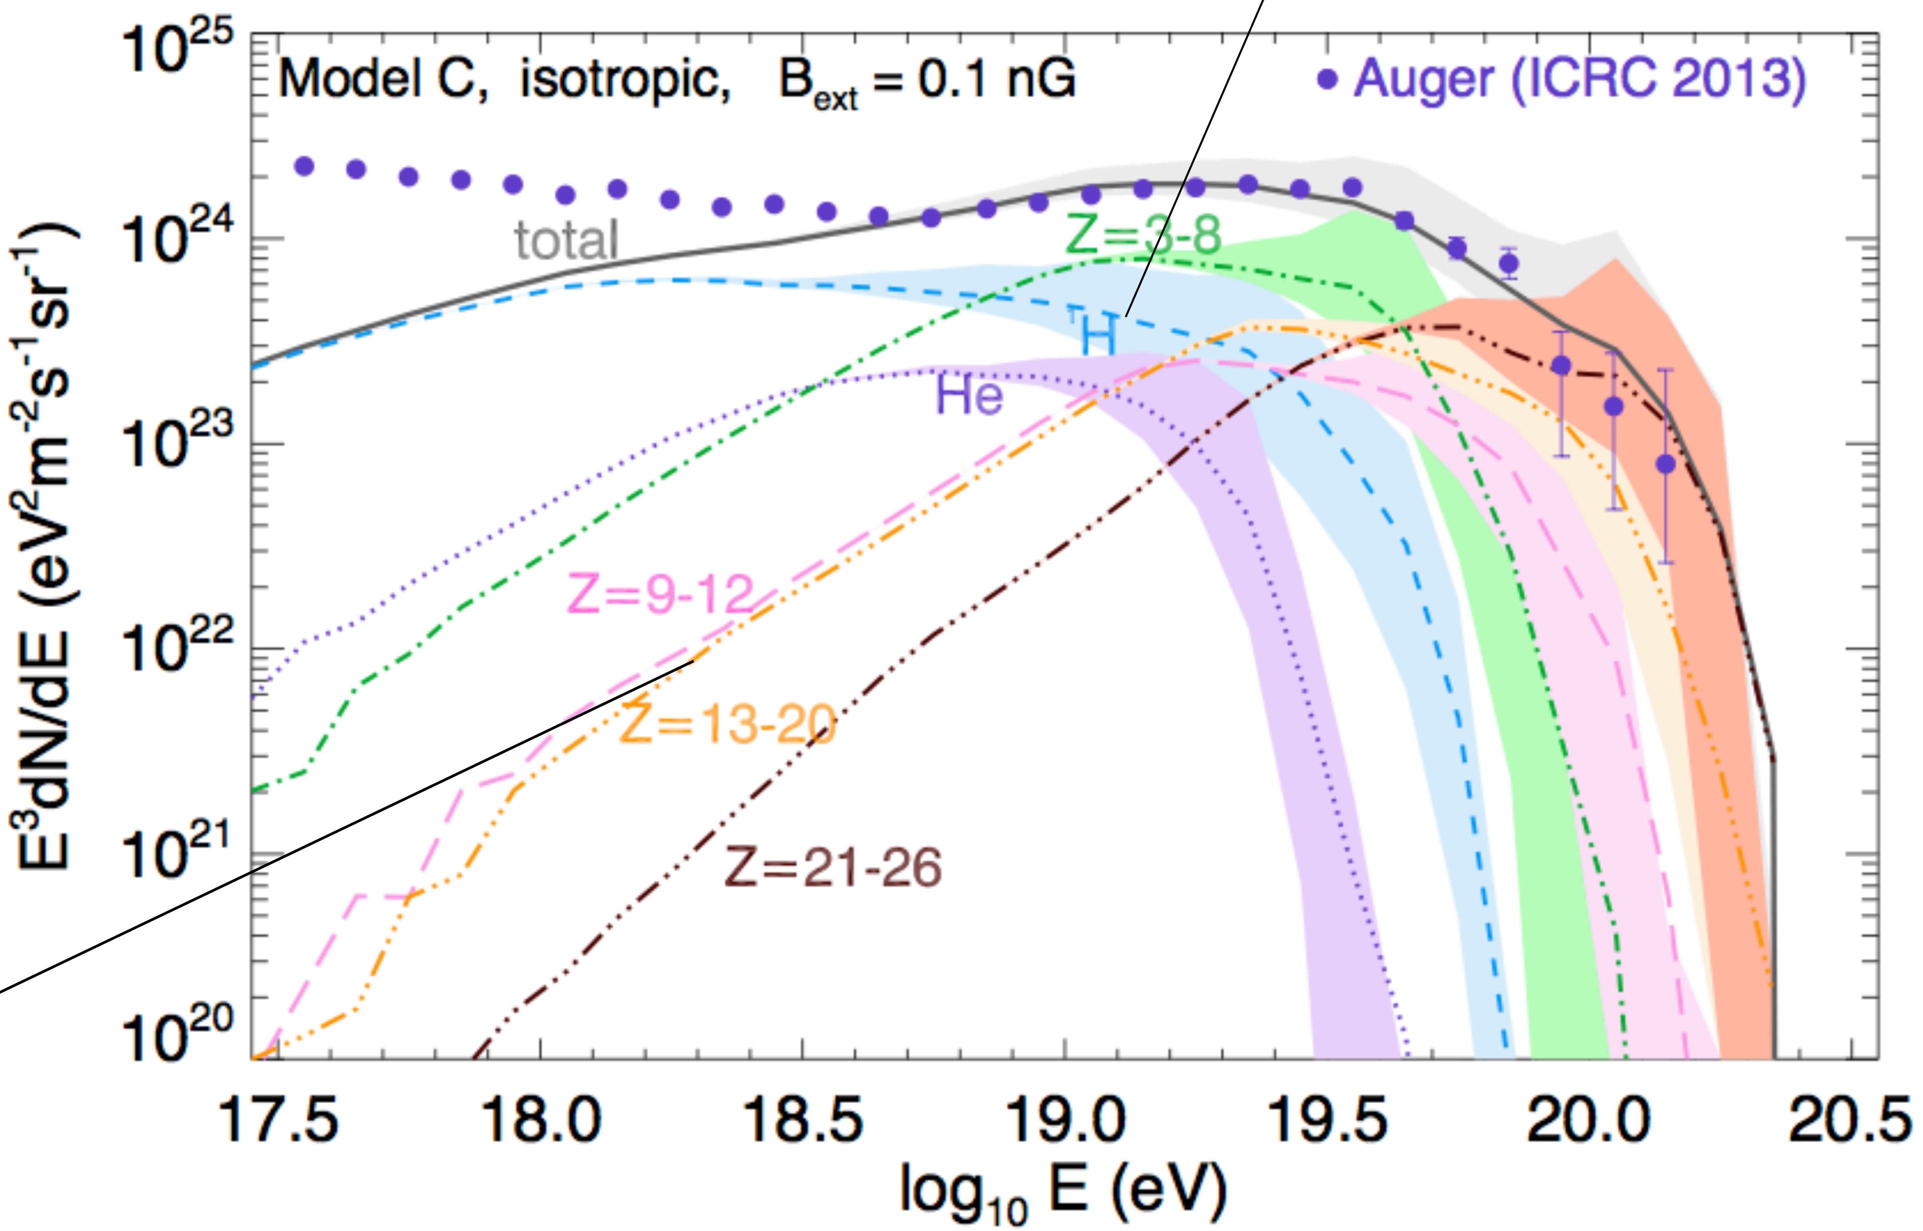
Phenomenological model : implications for the GCR to EGCR transition

low proton maximum energy
—> composition getting heavier as the energy increases



Phenomenological model : implications for the GCR to EGCR transition

low proton maximum energy
—> composition getting heavier as the energy increases

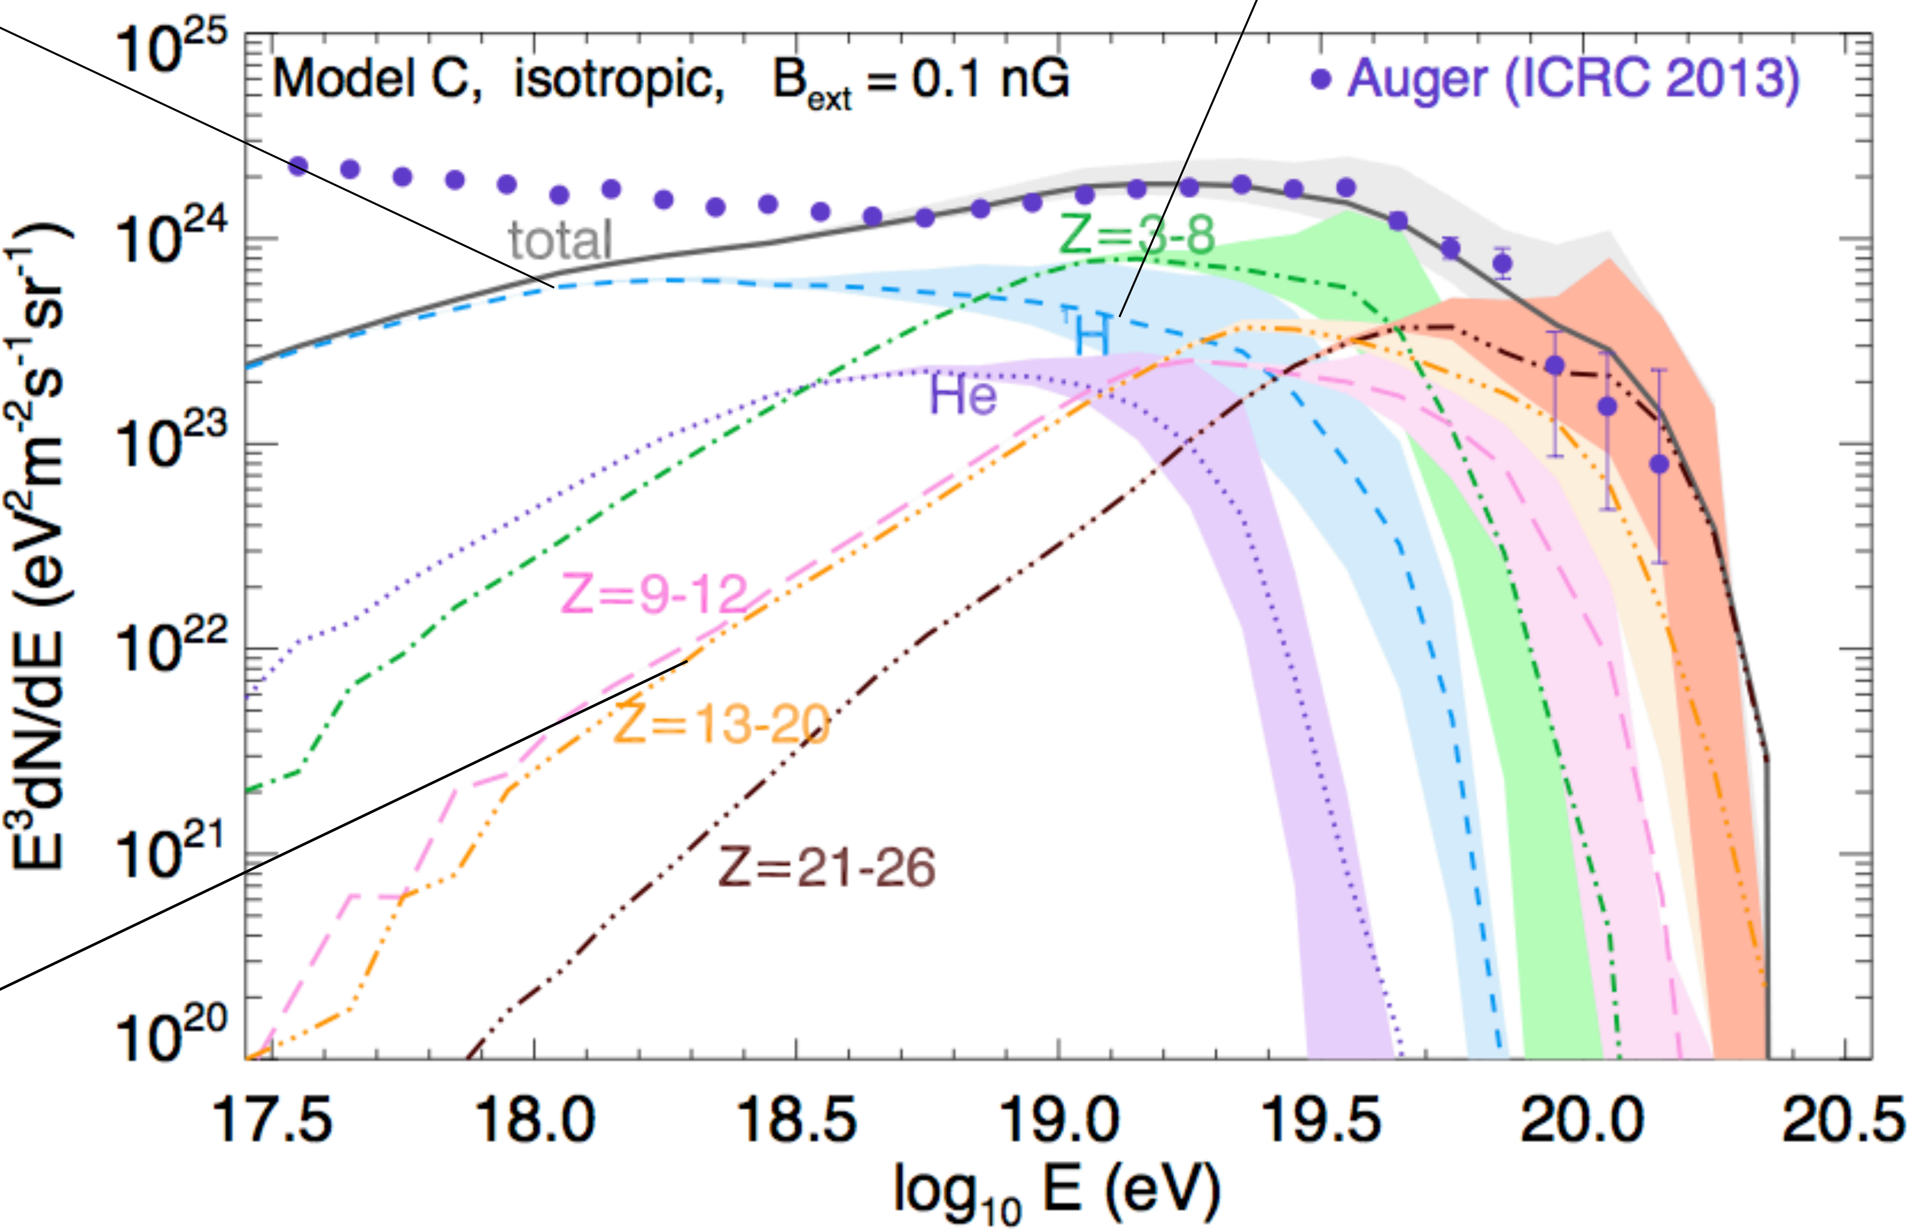


Heavier nuclei spectrum : Very hard due to the high-pass filter effect of the escape process
—> Hard nuclei spectrum required to fit Auger composition at high energy

Phenomenological model : implications for the GCR to EGCR transition

Proton spectrum : Soft due to the efficient escape of neutrons from the source (secondary neutron from the photodisintegration of nuclei within the source)
—> Allows the proton component to extend down to the light ankle seen by KASCADE-Grande

low proton maximum energy
—> composition getting heavier as the energy increases



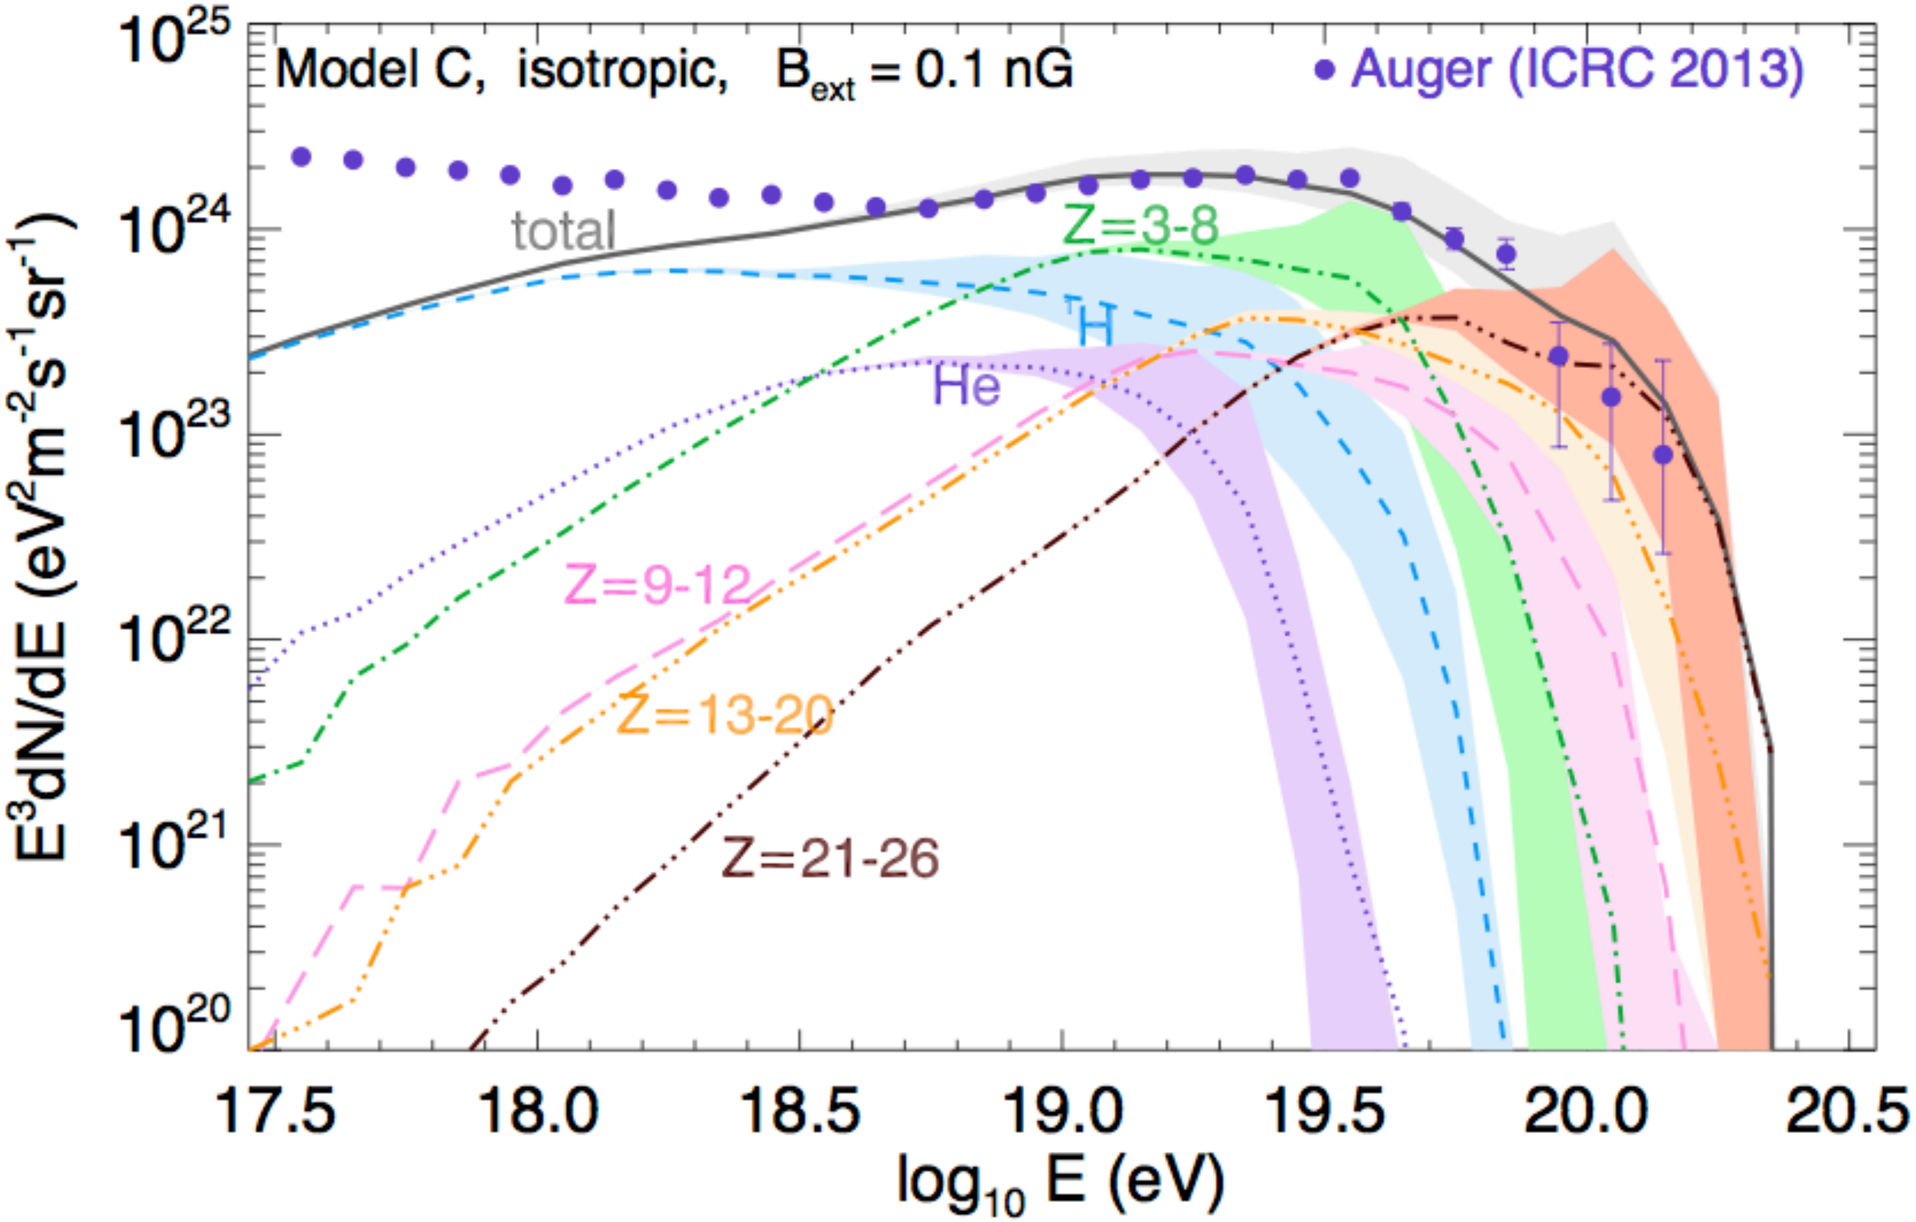
Heavier nuclei spectrum : Very hard due to the high-pass filter effect of the escape process
—> Hard nuclei spectrum required to fit Auger composition at high energy

Phenomenological model : implications for the GCR to EGCR transition

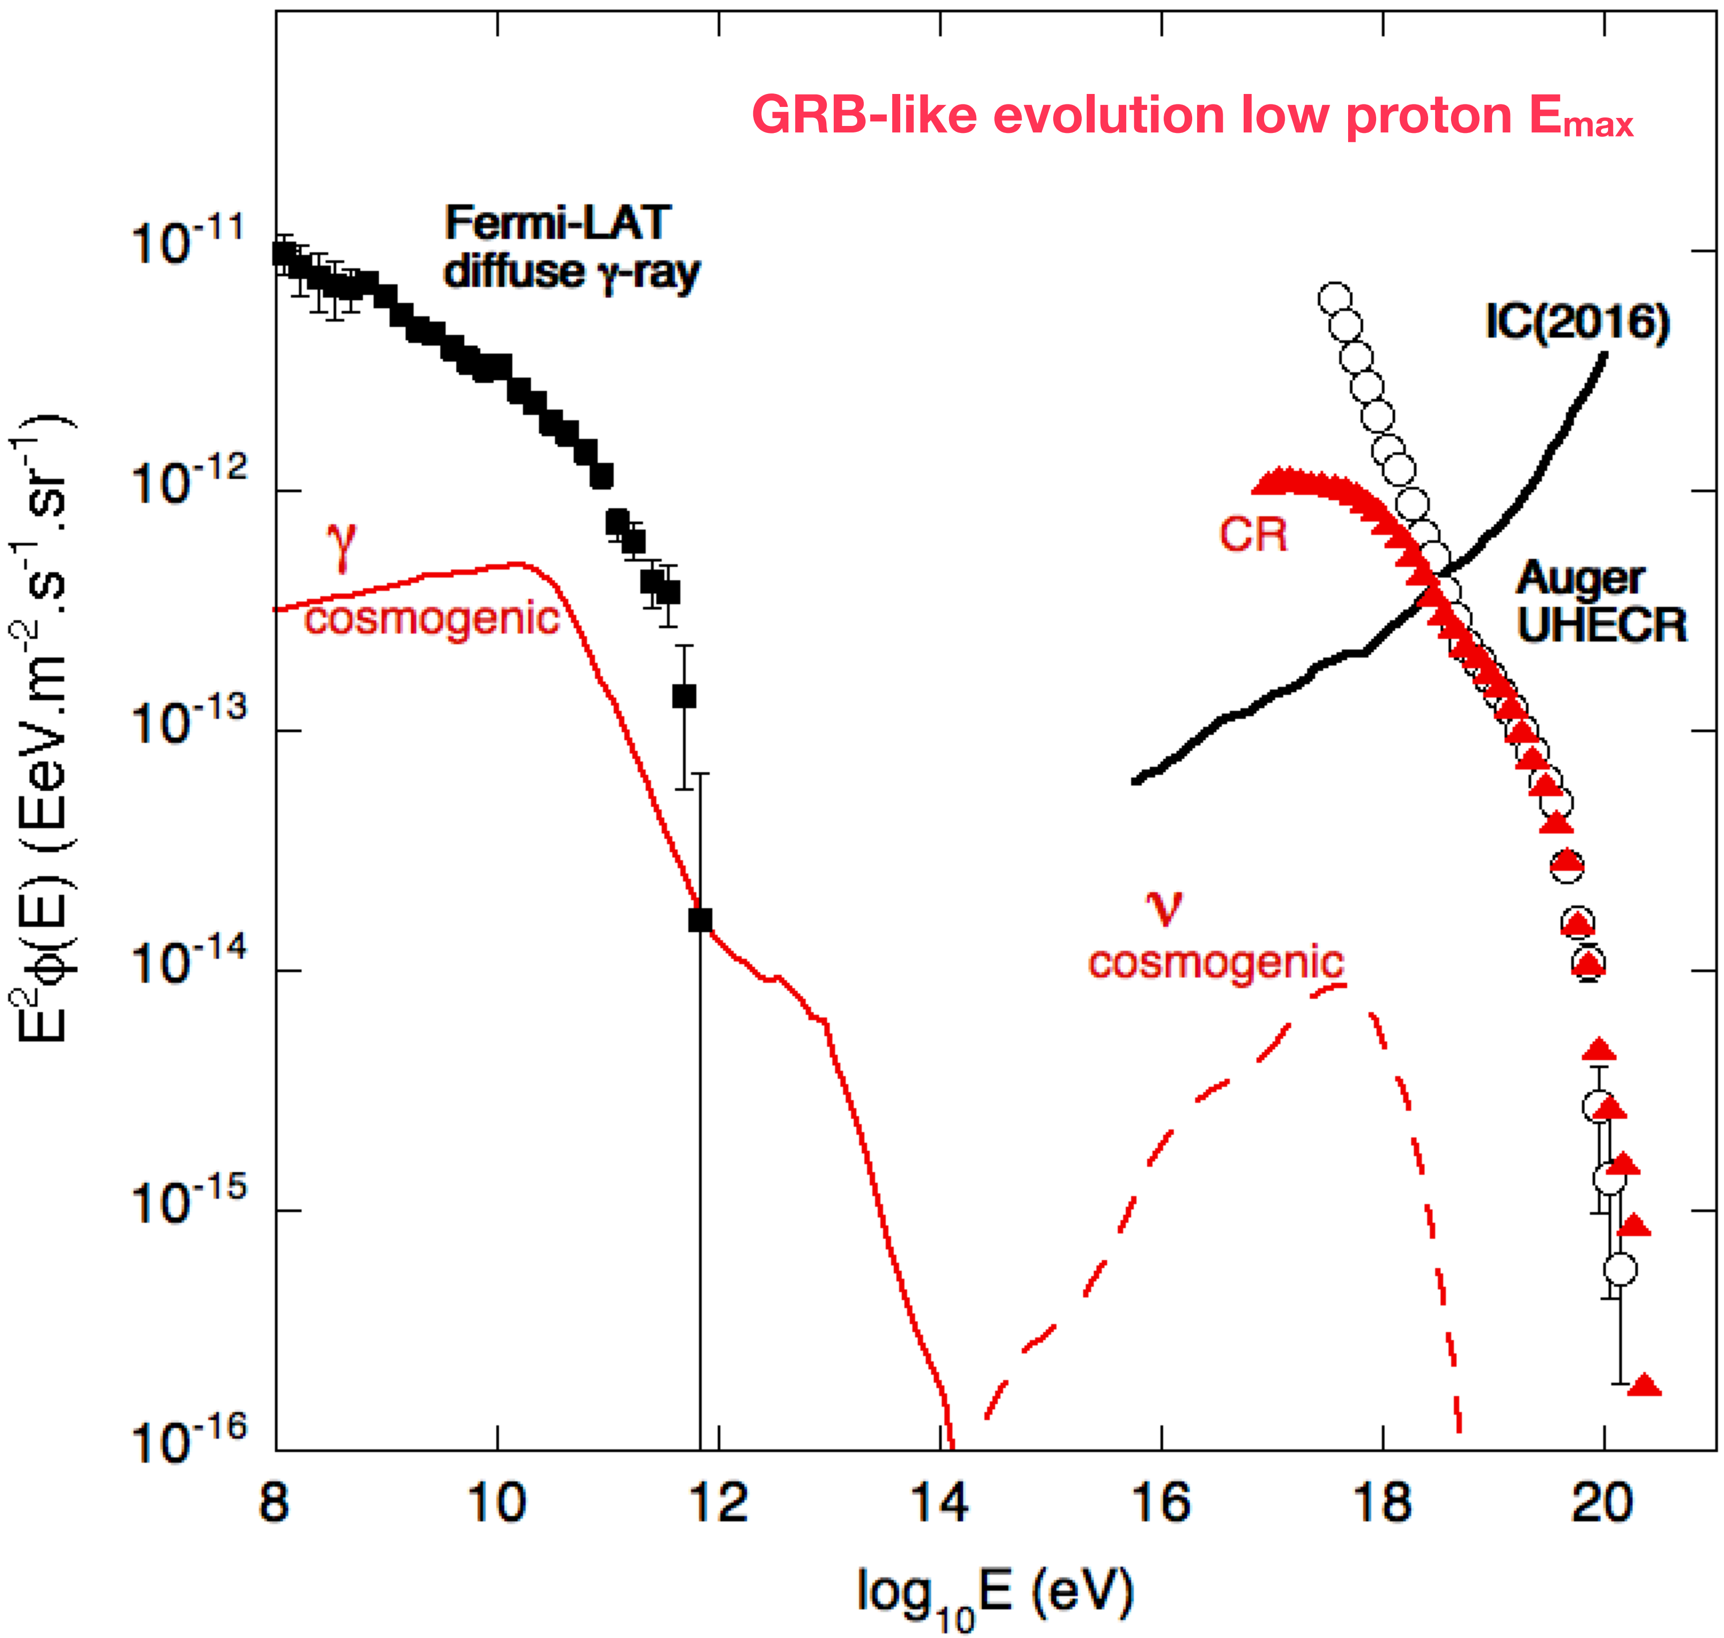
The difference in shape between the proton and nuclei spectra arises from the fact that the source environment is strongly magnetized and harbours dense radiation fields
—> should not be a distinctive feature of GRB sources

We showed that an extragalactic component presenting these spectral features was able to account for the light ankle and the evolution of the composition measured by Auger

Globus, Allard & Parizot, 2015, PRD rapid com.



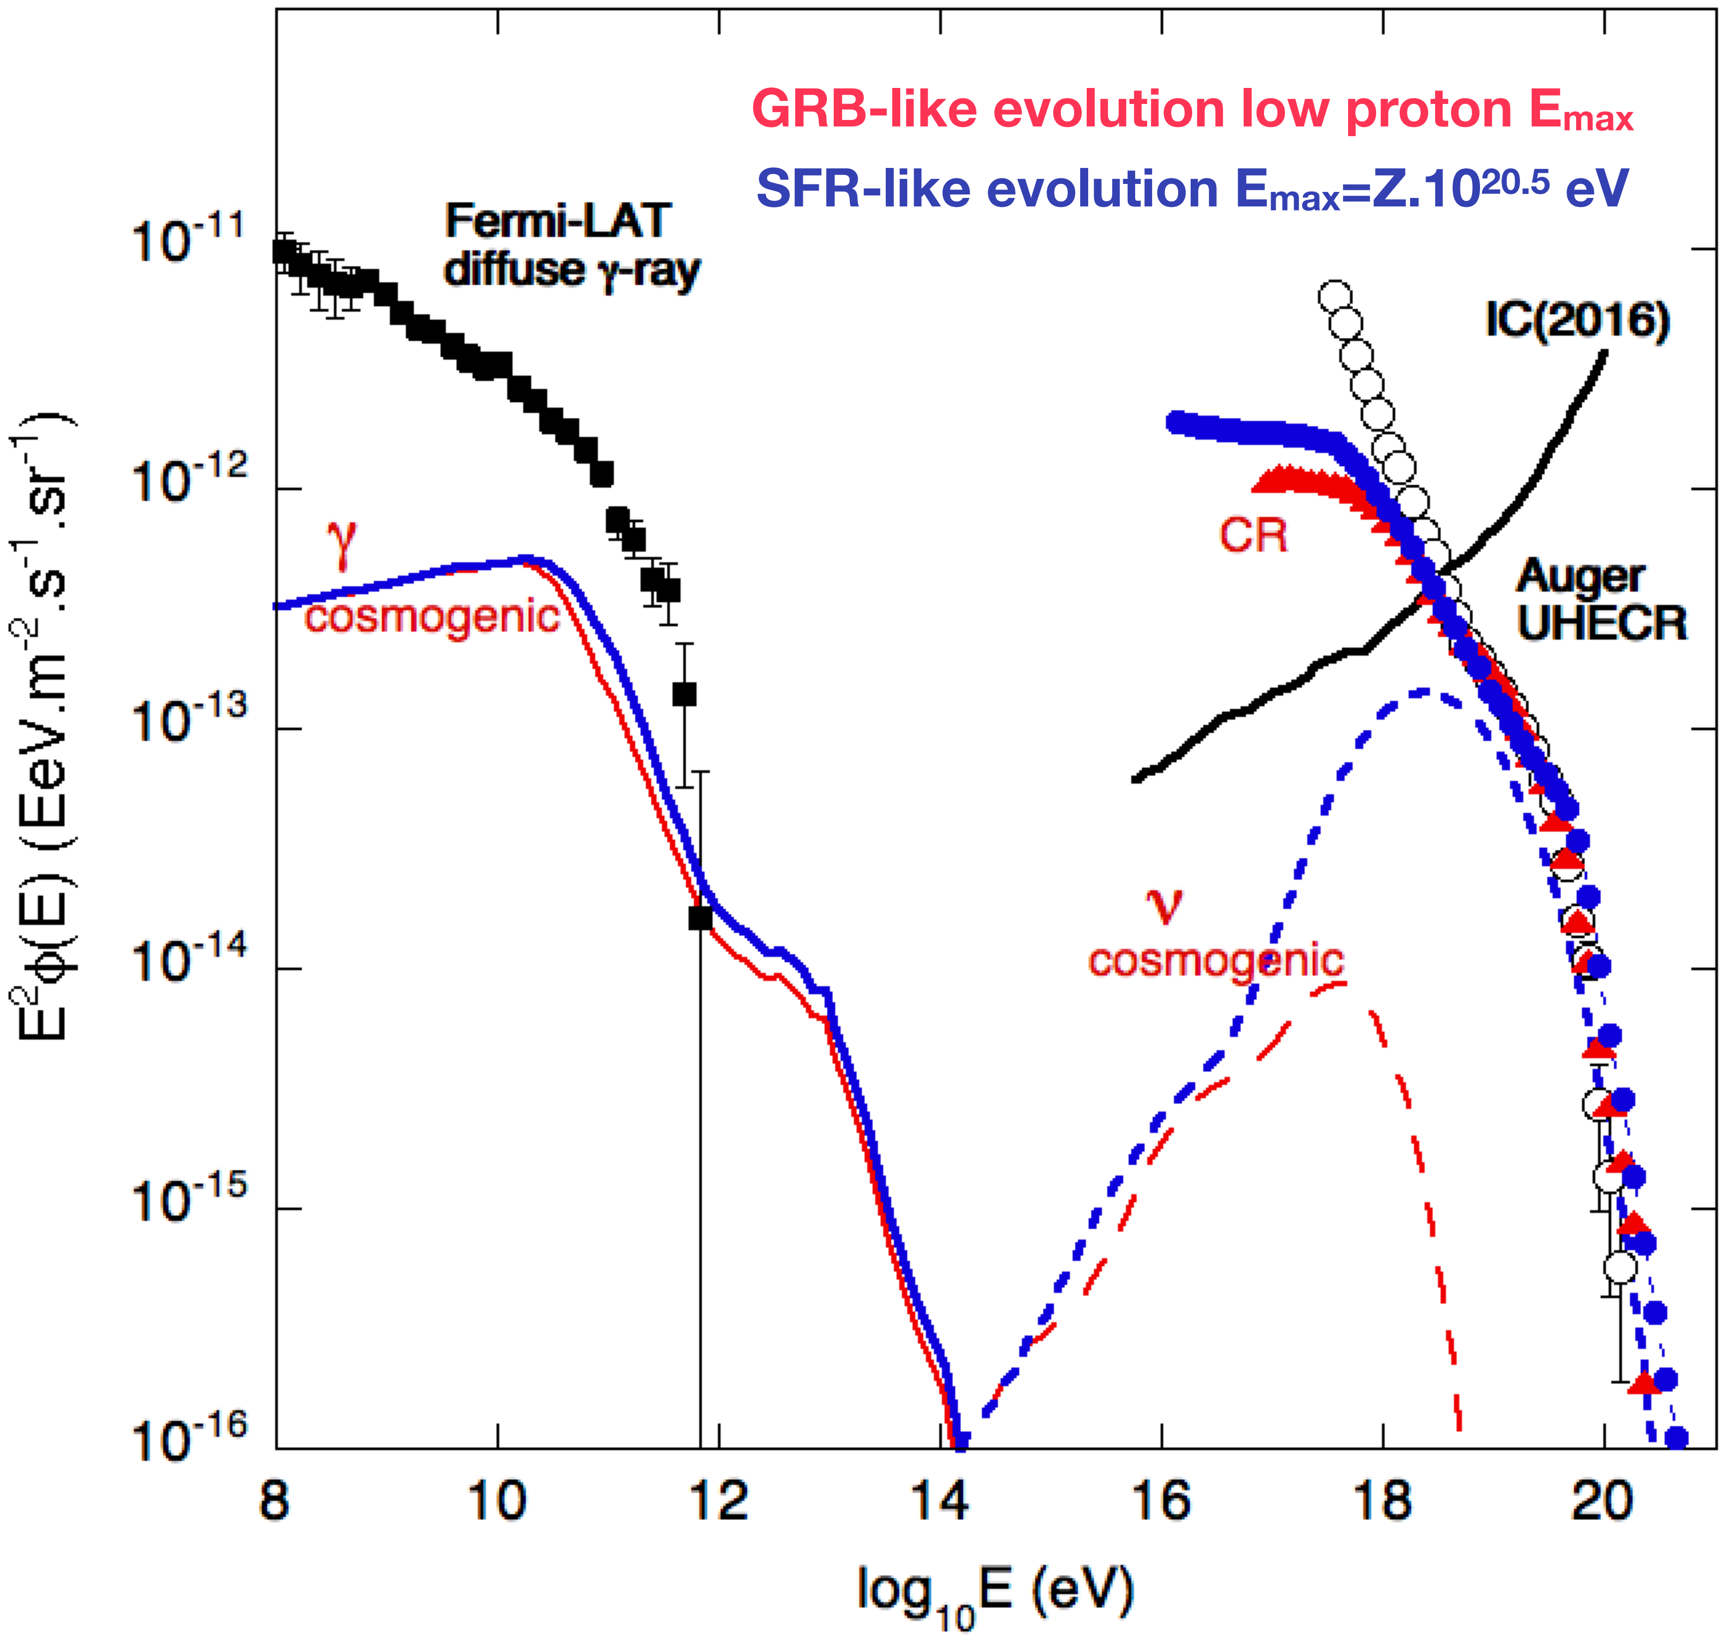
Phenomenological model : multi-messenger implications



The impact is, as expected, very strong on the predicted cosmogenic neutrino fluxes

Despite the low maximum energy per nucleon, the diffuse γ-ray flux is very similar to that of previous mixed composition case

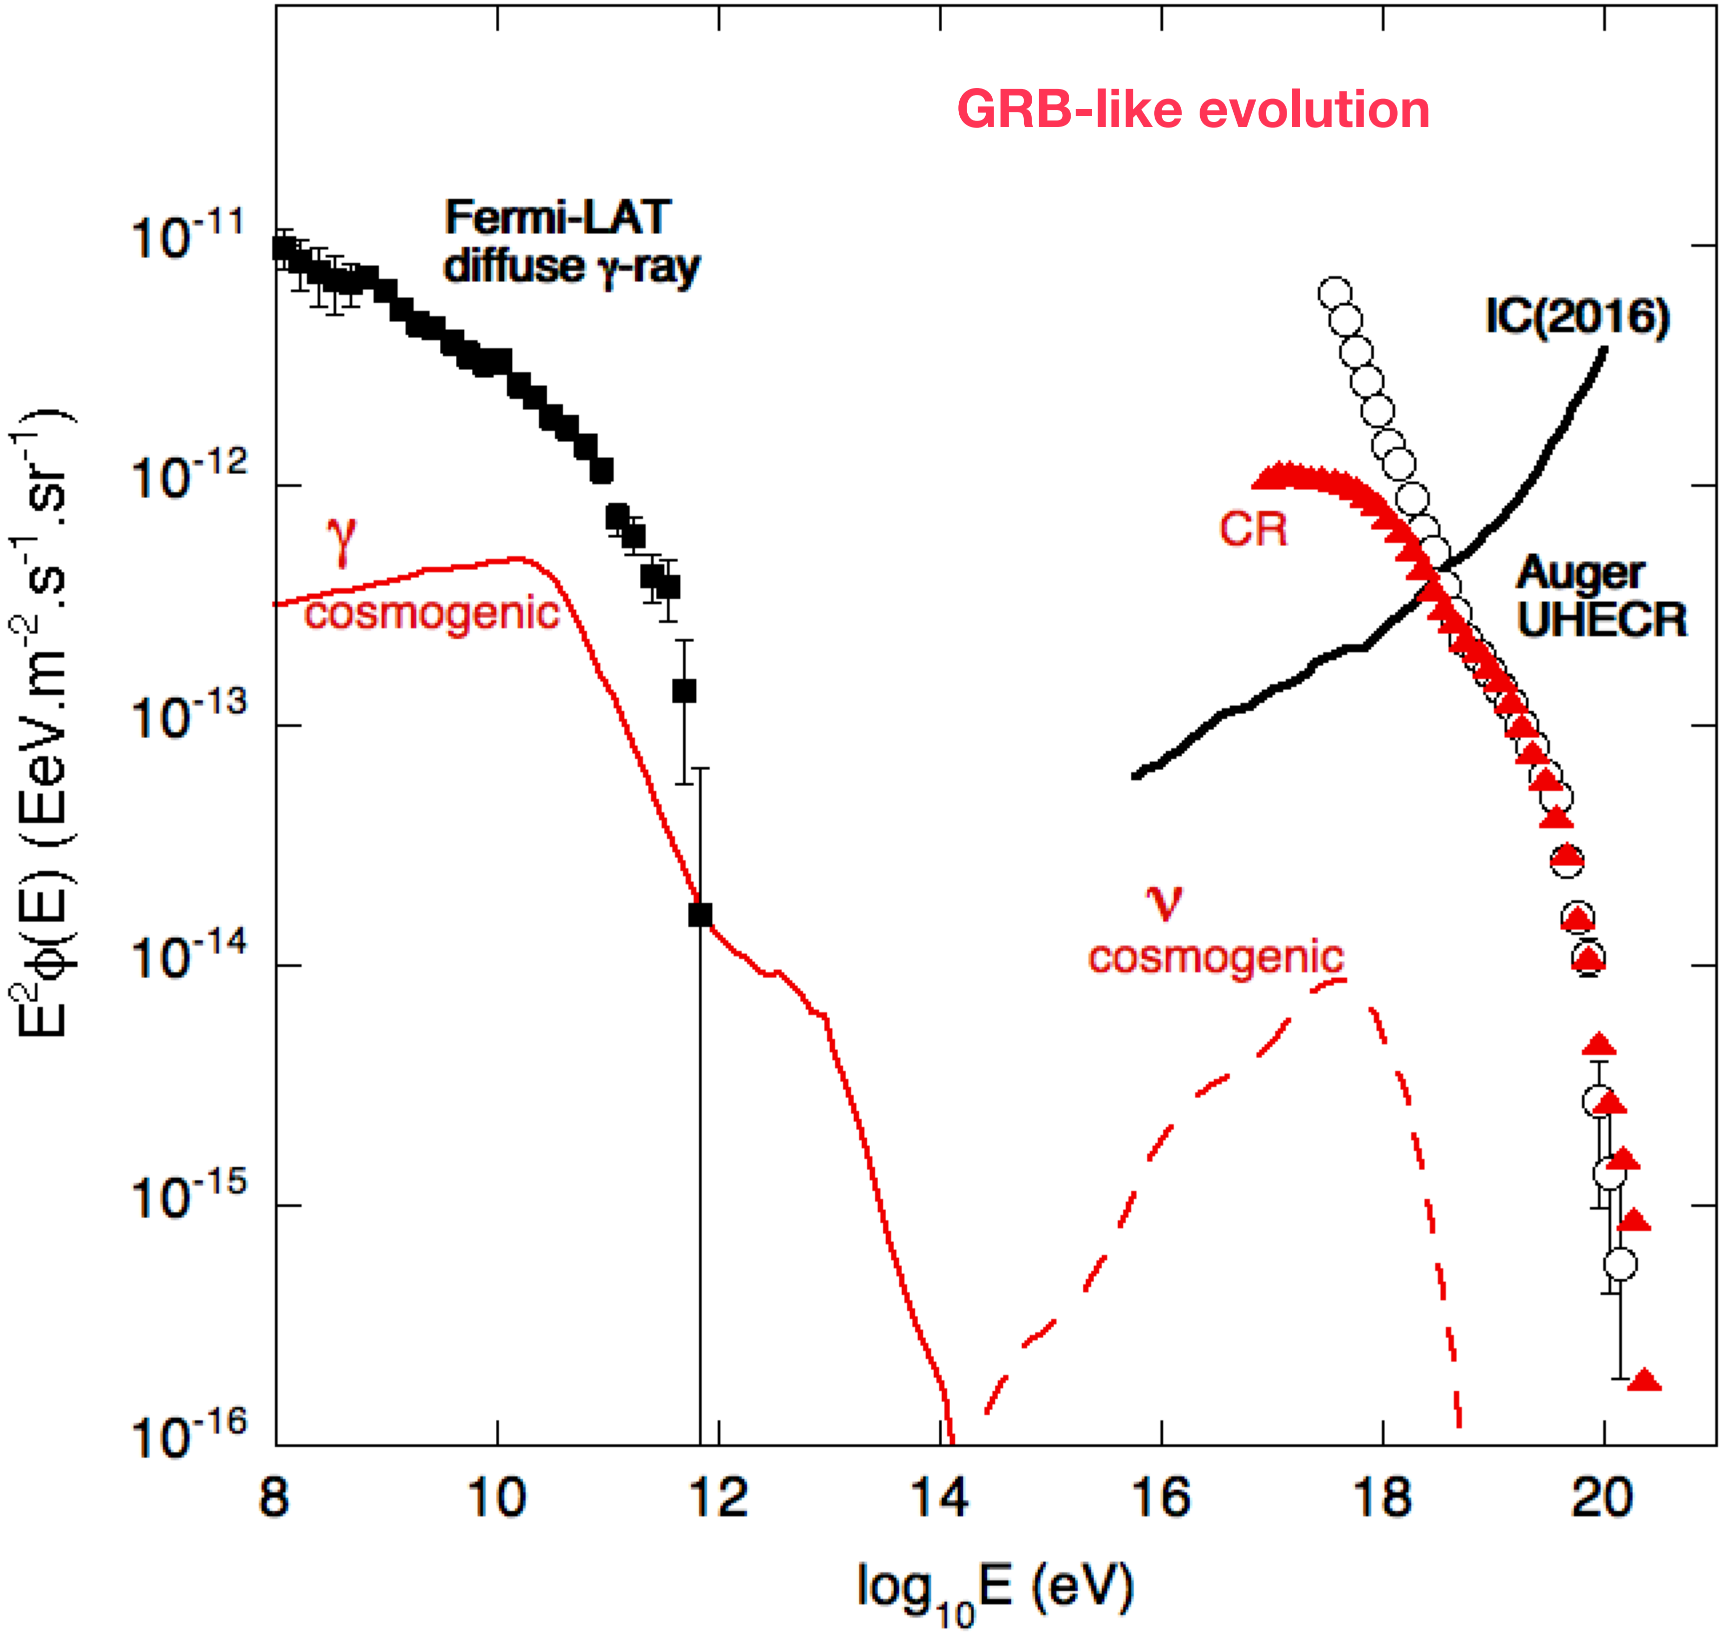
Phenomenological model : multi-messenger implications



The impact is, as expected, very strong on the predicted cosmogenic neutrino fluxes

Despite the low maximum energy per nucleon, the diffuse γ-ray flux is very similar to that of previous mixed composition case

Phenomenological model : multi-messenger implications



The impact is, as expected, very strong on the predicted cosmogenic neutrino fluxes

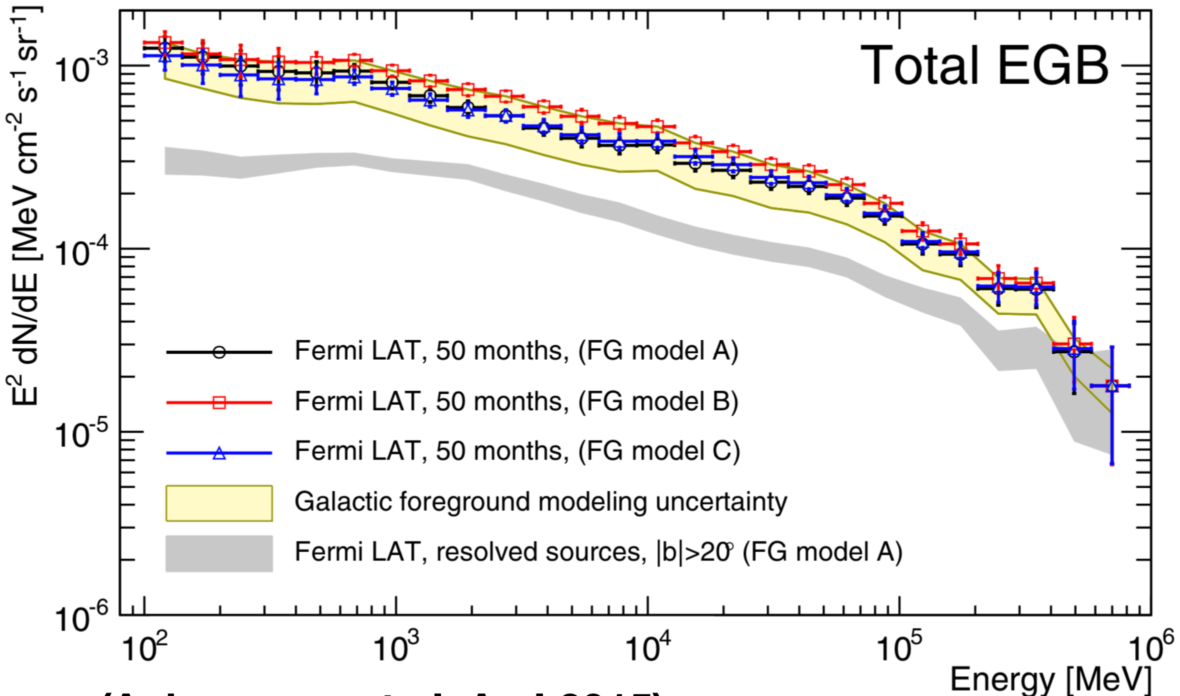
Despite the low maximum energy per nucleon, the diffuse γ-ray flux is very similar to that of previous mixed composition case

This scenario looks completely unconstrained from the point of view of cosmogenic neutrinos and photons

But Fermi-LAT data contain more informations than what we just discussed

Composition of the extragalactic γ-ray background

Fermi estimate of the total extragalactic γ-ray background (unresolved + resolved components)



(Ackermann et al. ApJ 2015)

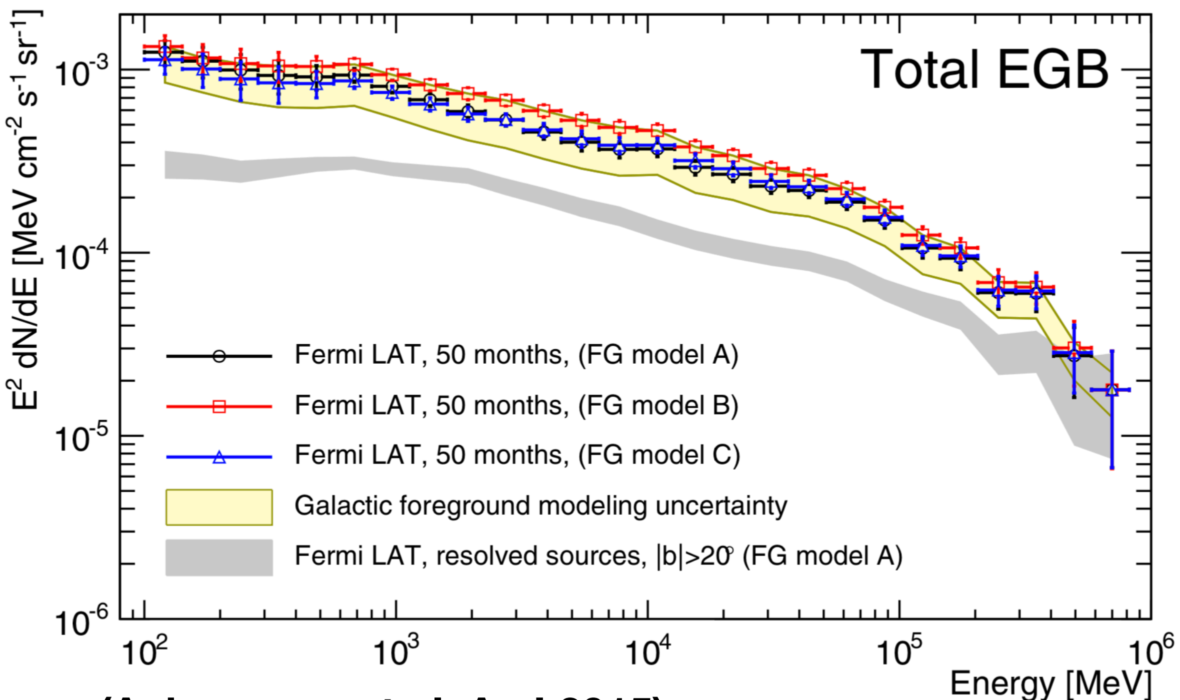
Account of the uncertainties on the modelling of the galactic foreground

➡3 different estimates (models A, B and C) corresponding to three equally realistic theoretical modelings of the galactic foreground

➡ In the following we consider only the largest estimated background (namely model B) to discuss the constrains brought by the EGB composition on UHECR origin

Composition of the extragalactic γ-ray background

Fermi estimate of the total extragalactic γ-ray background (resolved + unresolved components)



(Ackermann et al. ApJ 2015)

The total extragalactic γ-ray background is made of several contributions :

- resolved point sources (very large majority of Blazars)
- unresolved point sources (mostly blazars, misaligned AGNs and star forming galaxies)
- truly diffuse processes (UHECR for sure, possibly DM)

➡ **estimating the different contributions would help constraining that of UHECRs**

Different estimates from Fermi data of the contribution of blazar point sources (resolved and unresolved) to the total γ-ray background were proposed

2 recent studies:

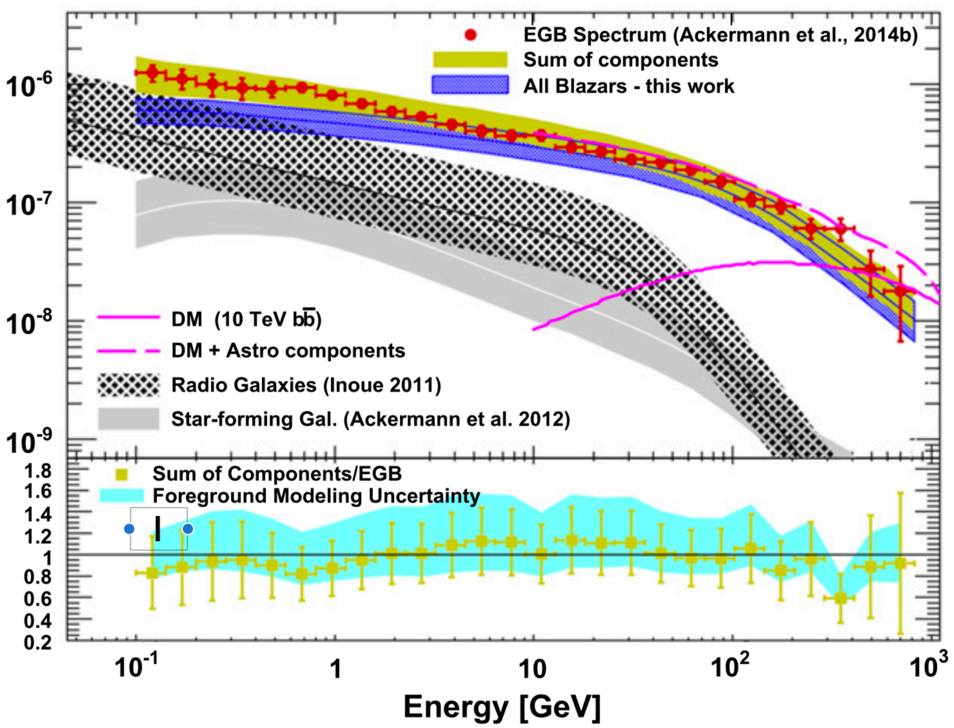
- Ackermann et al. , PRL, 2016 (**A16**)
- Zechlin et al., ApJ, 2016 (**Z16**)

(based on a method proposed in Malyshev & Hogg 2011)

	(Z16)					**(A16)**
Energy bands (in GeV)	① 1.04–1.99	② 1.99–5.0	③ 5.0–10.4	④ 10.4–50	⑤ 50–171	⑥ 50–2000
F_{PS} $(\times 10^{-9}\,cm^{-2}\cdot s^{-1}\cdot sr^{-1})$	250^{+20}_{-40}	124^{+7}_{-25}	27^{+8}_{-3}	14^{+6}_{-1}	$1.7^{+1.1}_{-0.4}$	$2.07^{+0.40}_{-0.34}$
F_{PS}/F_{EGB} (% Model B)	68^{+5}_{-10}	63^{+4}_{-13}	52^{+15}_{-6}	51^{+22}_{-4}	65^{+41}_{-15}	71^{+13}_{-12}

Besides blazars, SFGs and misaligned AGNs should contribute significantly to the EGB but these contributions were not constrained by **A16 and Z16**

Composition of the extragalactic γ-ray background



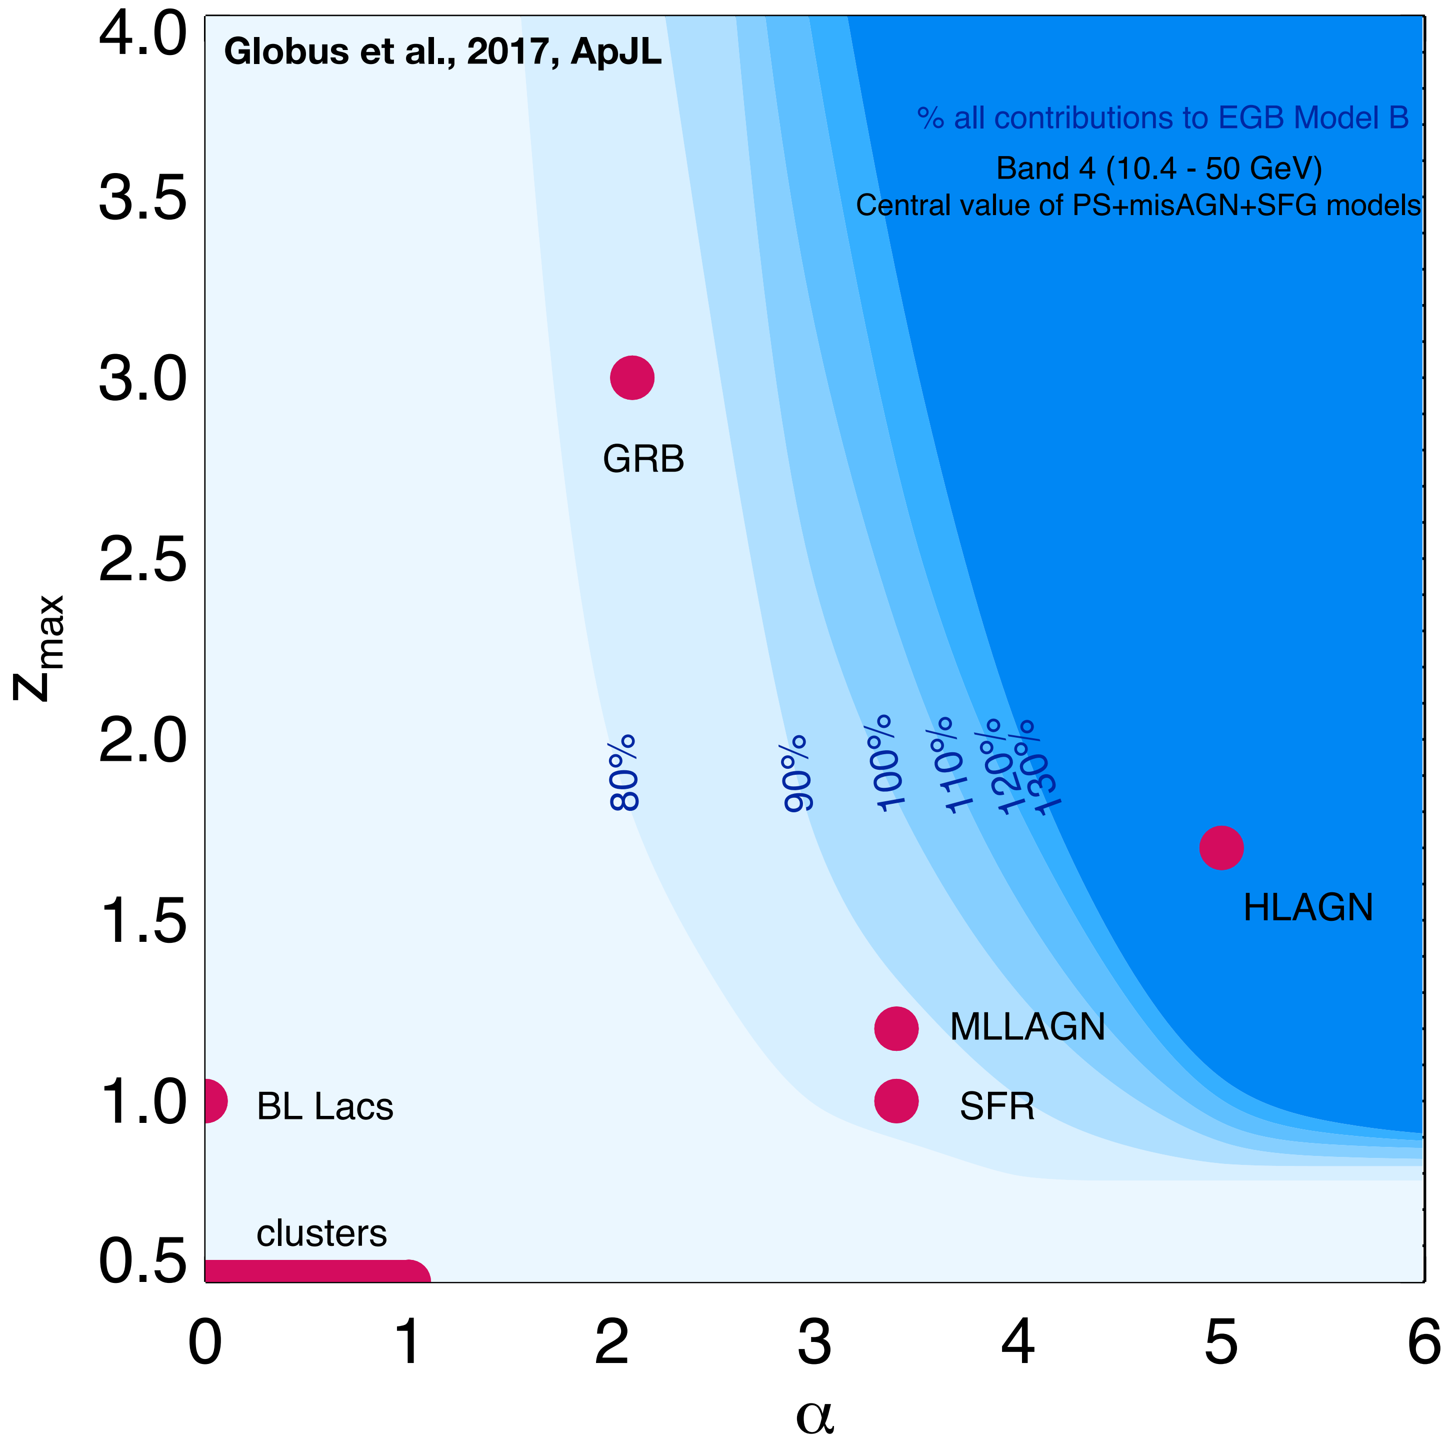
Ajello et al., ApJ, 2015

	(Z16)					(A16)
Energy bands (in GeV)	① 1.04–1.99	② 1.99–5.0	③ 5.0–10.4	④ 10.4–50	⑤ 50–171	⑥ 50–2000
$F_{\rm PS}$ $(\times 10^{-9}\,{\rm cm^{-2}\cdot s^{-1}\cdot sr^{-1}})$	250^{+20}_{-40}	124^{+7}_{-25}	27^{+8}_{-3}	14^{+6}_{-1}	$1.7^{+1.1}_{-0.4}$	$2.07^{+0.40}_{-0.34}$
$F_{\rm PS}/F_{\rm EGB}$ (% Model B)	68^{+5}_{-10}	63^{+4}_{-13}	52^{+15}_{-6}	51^{+22}_{-4}	65^{+41}_{-15}	71^{+13}_{-12}
$F_{\rm SFG+misAGN}$ $(\times 10^{-9}\,{\rm cm^{-2}\cdot s^{-1}\cdot sr^{-1}})$	94^{+100}_{-36}	44^{+49}_{-18}	10^{+12}_{-4}	$4.5^{+5.4}_{-1.9}$	$0.17^{+0.18}_{-0.07}$	$0.18^{+0.19}_{-0.07}$
$F_{\rm SFG+misAGN}/F_{\rm EGB}$ (% Model B)	25^{+27}_{-10}	23^{+25}_{-9}	20^{+23}_{-8}	16^{+20}_{-7}	6^{+7}_{-3}	6^{+6}_{-2}

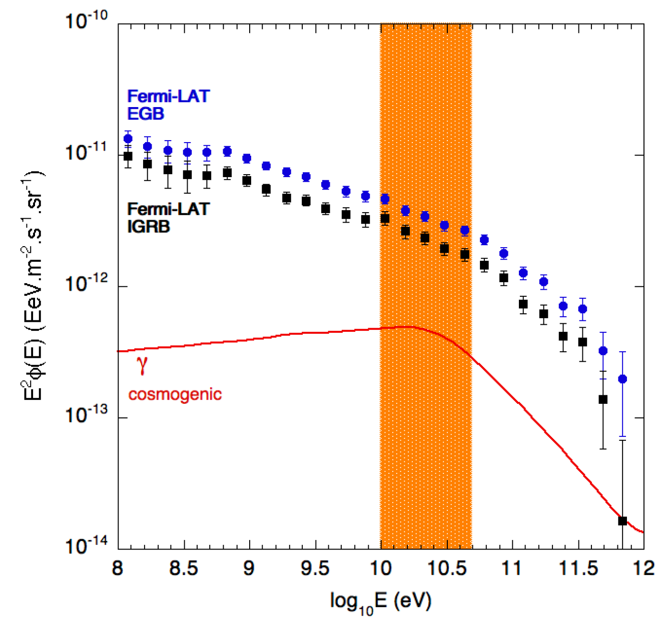
Using theoretical estimates of the contribution (almost exclusively unresolved) of SFG and misaligned AGNs one can add their contributions to that attributed to blazars in Z16 and A16

The contribution of UHECR must added to those of astrophysical sources to check whether or not a given astrophysical model is viable.

Summary plot on the allowed cosmological evolutions



Astrophysical sources evolution usually parametrised as :
$(1+z)^{\alpha}$
up to a redshift $\mathbf{z_{max}}$

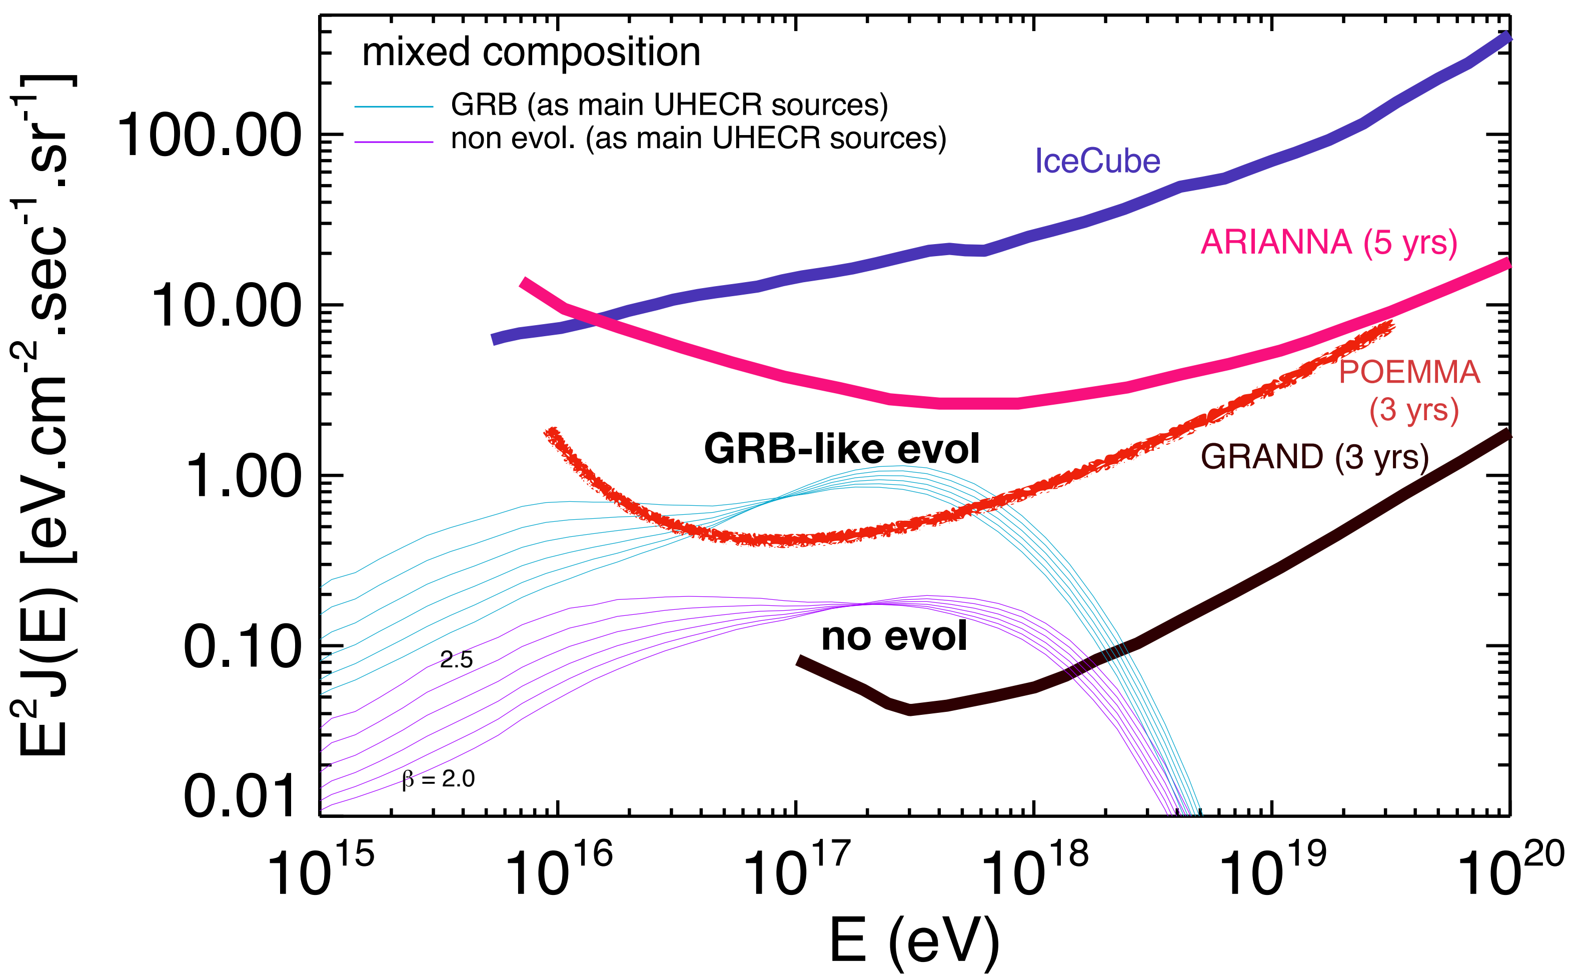


In the 10-50 GeV band, where the UHECR contribution to the EGRB is the largest

In the case of our UHECR model (transition and low Emax), only very strong evolutions such as that of very luminous AGNs are clearly disfavoured

Discussion of the resulting cosmogenic neutrino fluxes

Globus et al., 2017, ApJL

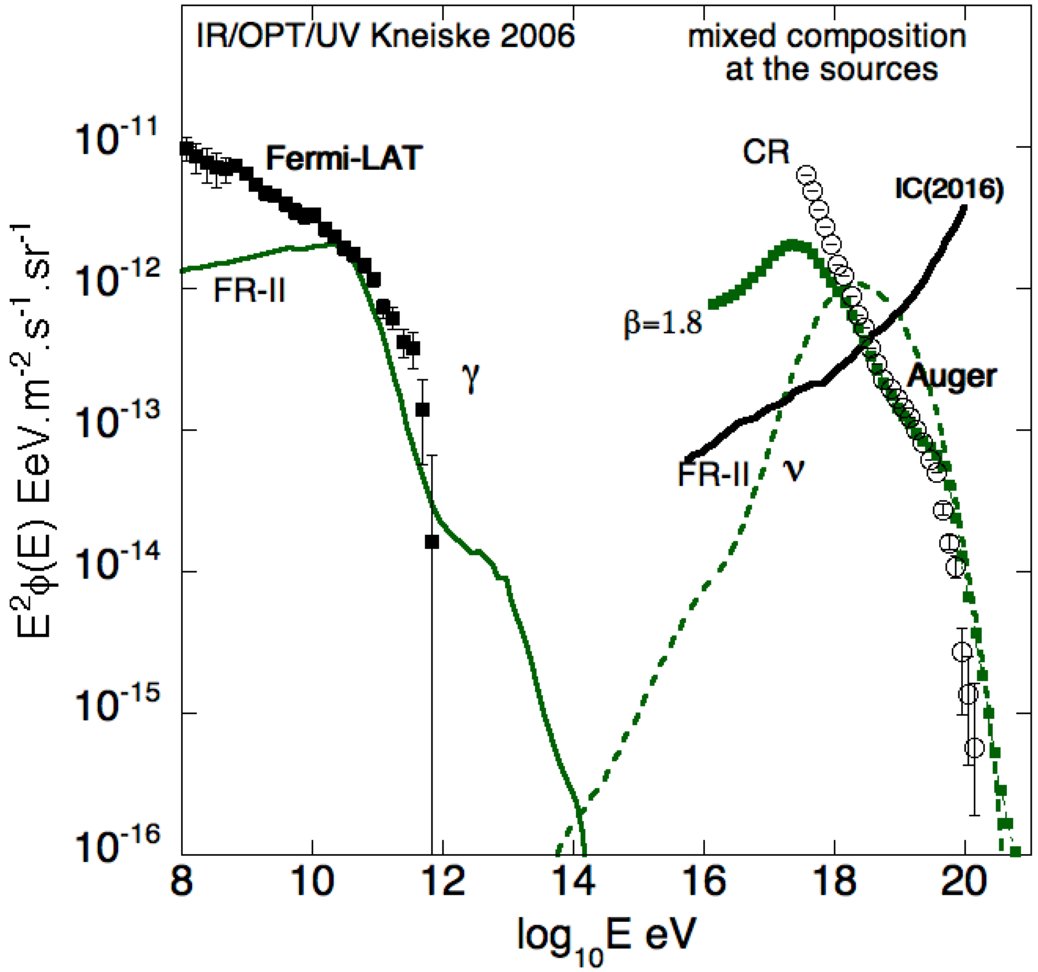


The range of cosmogenic neutrino fluxes predicted in the framework of our model are low (mostly due to the low value of the maximum energy per nucleon)

Not observable by current and mid-term experiments
POEMMA could see some neutrinos for GRB or SFR-like evolutions

However there is possibly more to observe than just the cosmogenic neutrinos from the dominant contribution to UHECRs

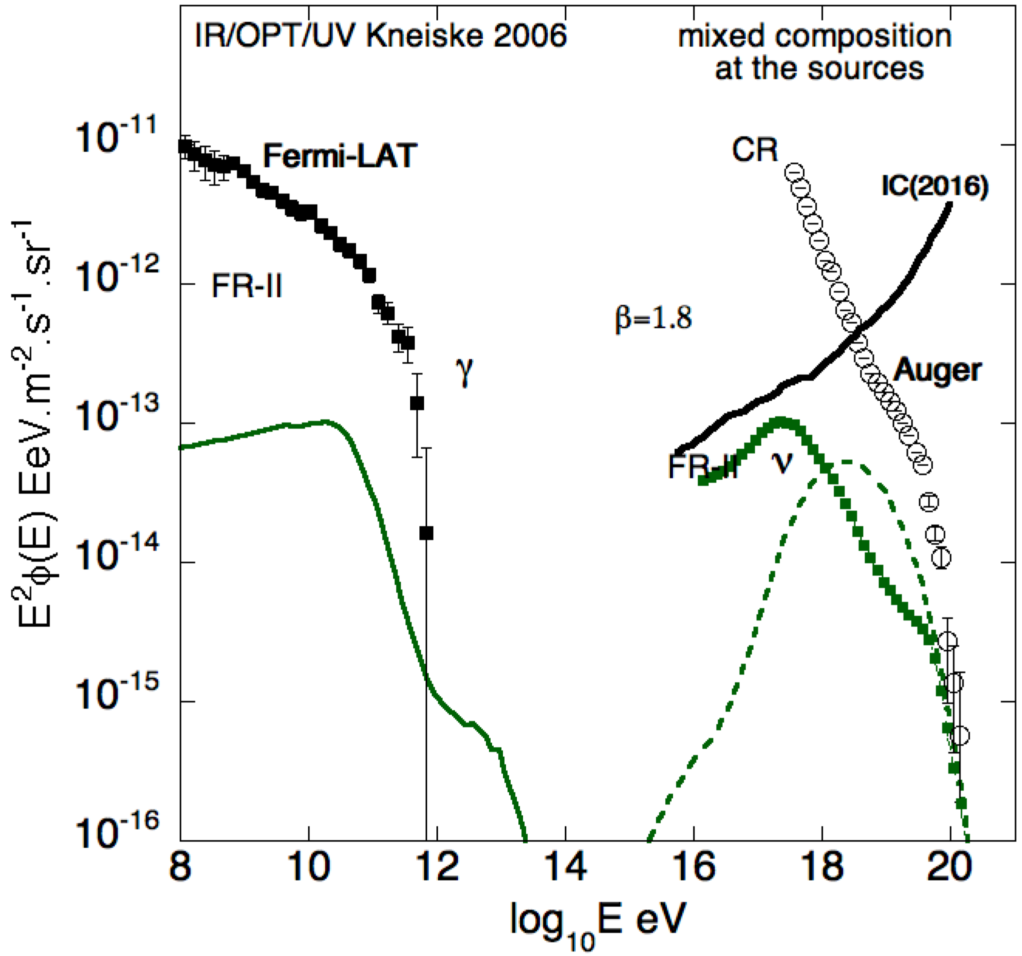
Constraining the presence of powerful protons accelerators in the universe



Let us consider proton accelerators (above 10^{20} eV) with a strong source evolution

- ➡ green curve is ruled out by Fermi, IceCube and Auger (composition)
- ➡ Let us instead assume it is a subdominant part of the spectrum, say 5% at 10^{19} eV

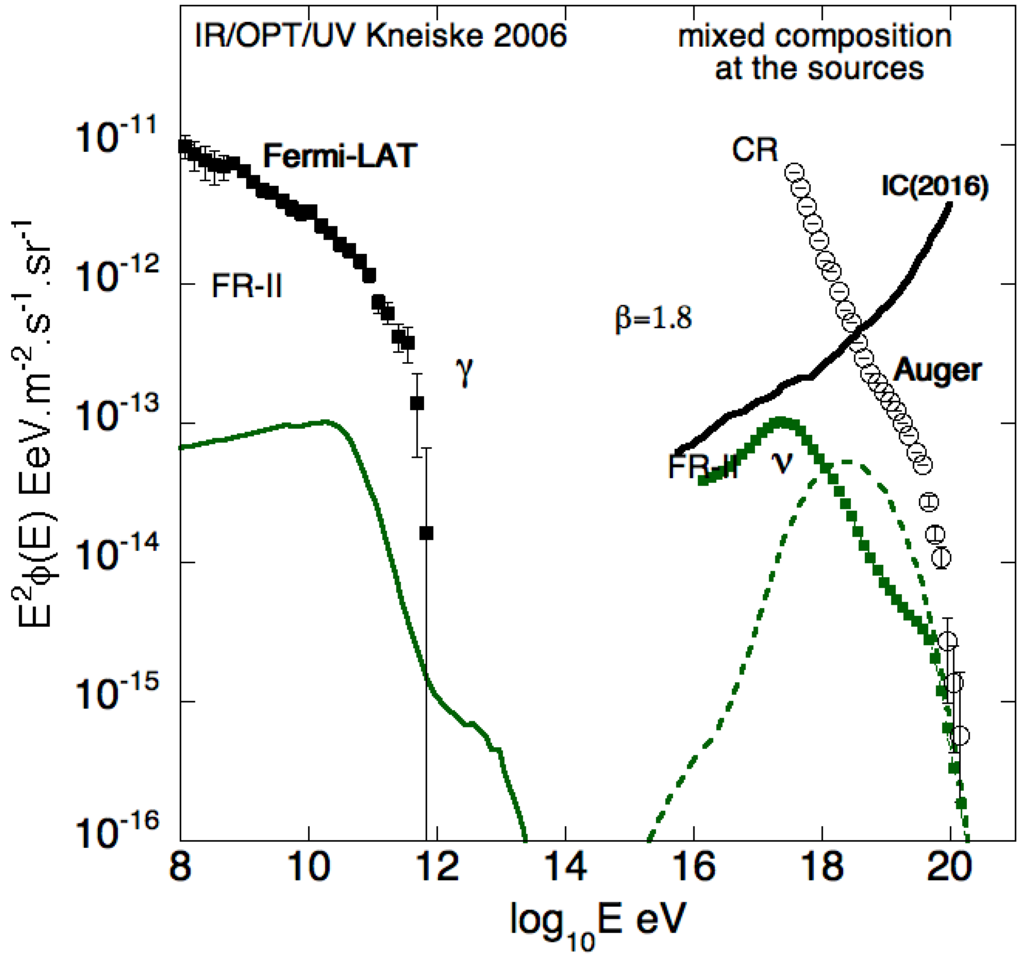
Constraining the presence of powerful protons accelerators in the universe



Let us consider proton accelerators (above 10^{20} eV) with a strong source evolution

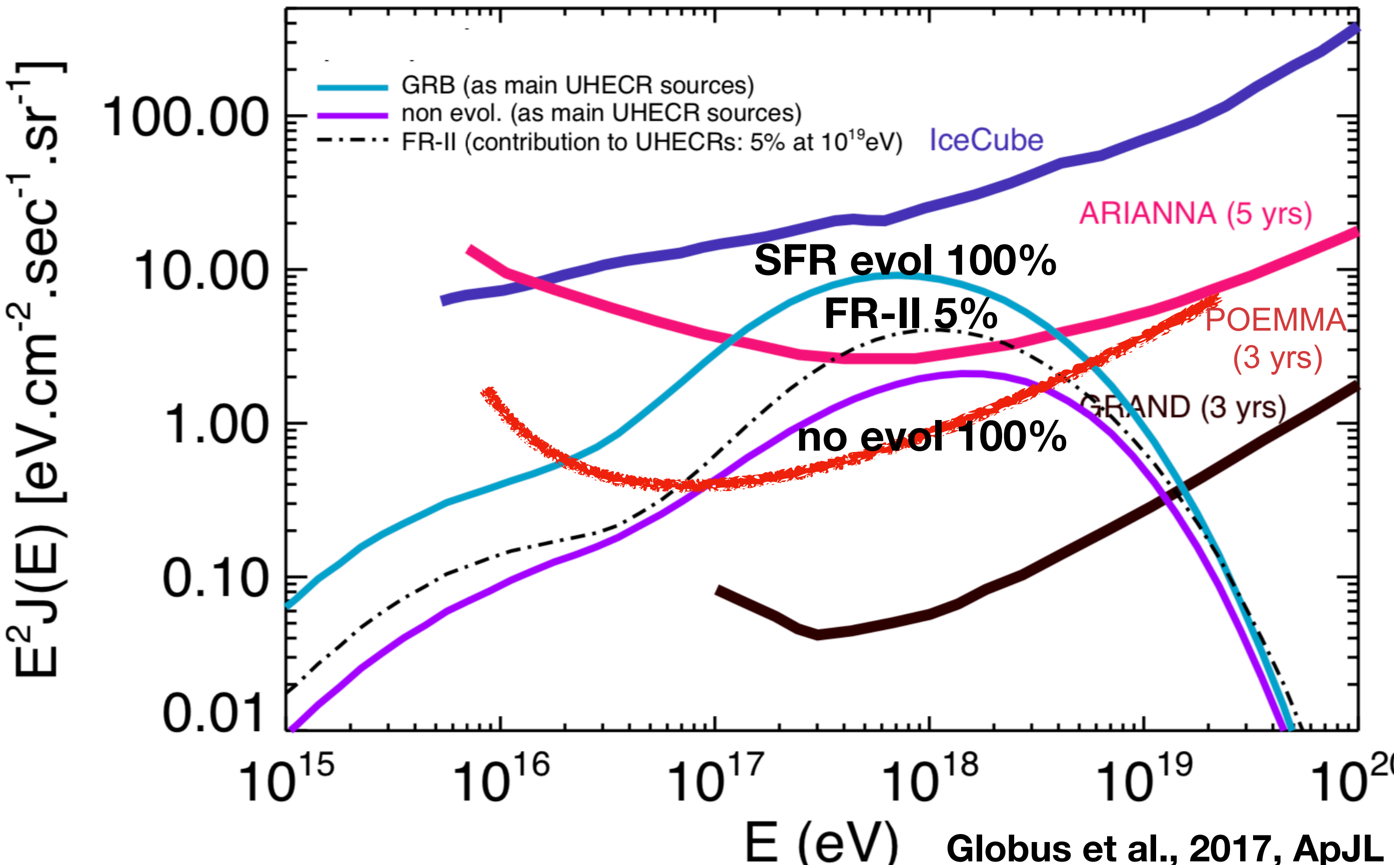
- ➡ Let us instead assume it is a subdominant part of the spectrum, say 5% at 10^{19} eV
- ➡ Then it is not ruled out anymore by any experimental constraint

Constraining the presence of powerful protons accelerators in the universe



Let us consider proton accelerators (above 10^{20} eV) with a strong source evolution

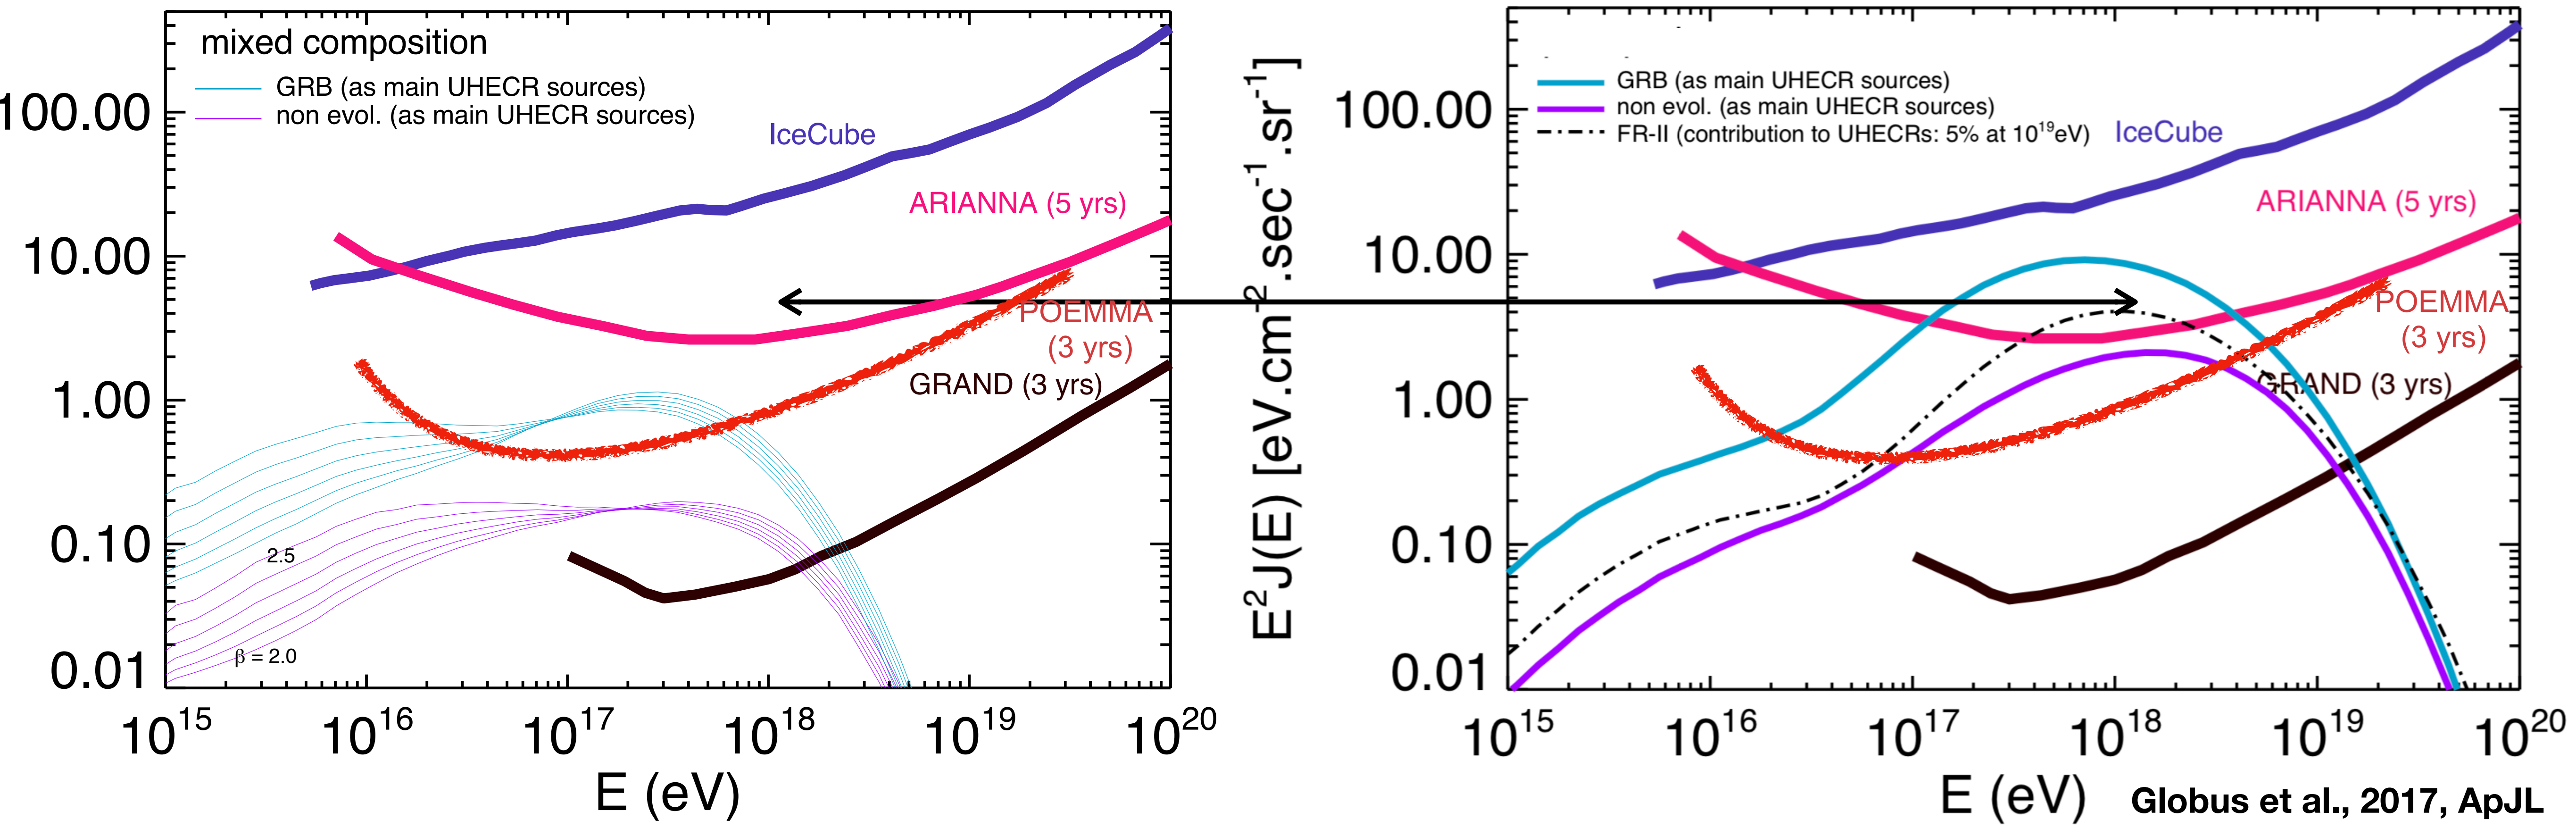
- ➡ Let us instead assume it is a subdominant part of the spectrum, say 5% at 10^{19} eV
- ➡ Then it is not ruled out anymore by any experimental constraint



The resulting neutrino flux is larger than that of a non evolving source scenario and 100% contribution to the UHECR spectrum

Constraining the presence of powerful protons accelerators in the universe

The resulting neutrino flux is significantly larger than that of the main UHECR component



Globus et al., 2017, ApJL

Real window to constrain the presence of proton accelerator in the universe
(and not only within the GZK horizon)

Thank you very much !!!!
cảm ơn bạn rất nhiều
Many thanks to the organisers and the staff !!!

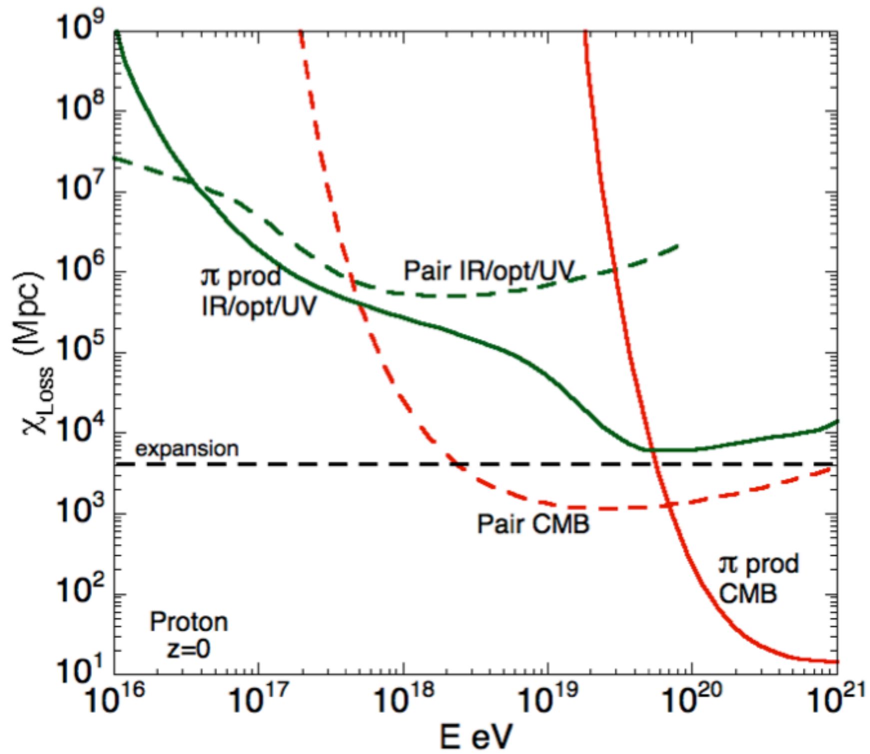
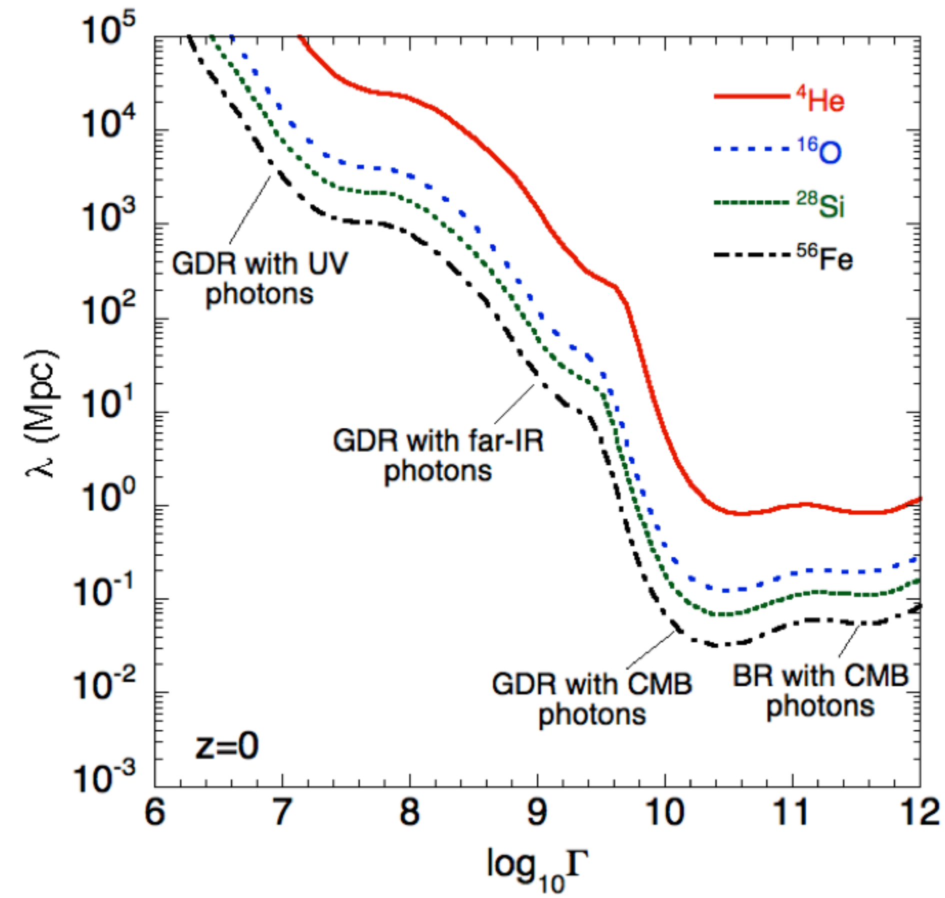
The GZK effect for protons and nuclei



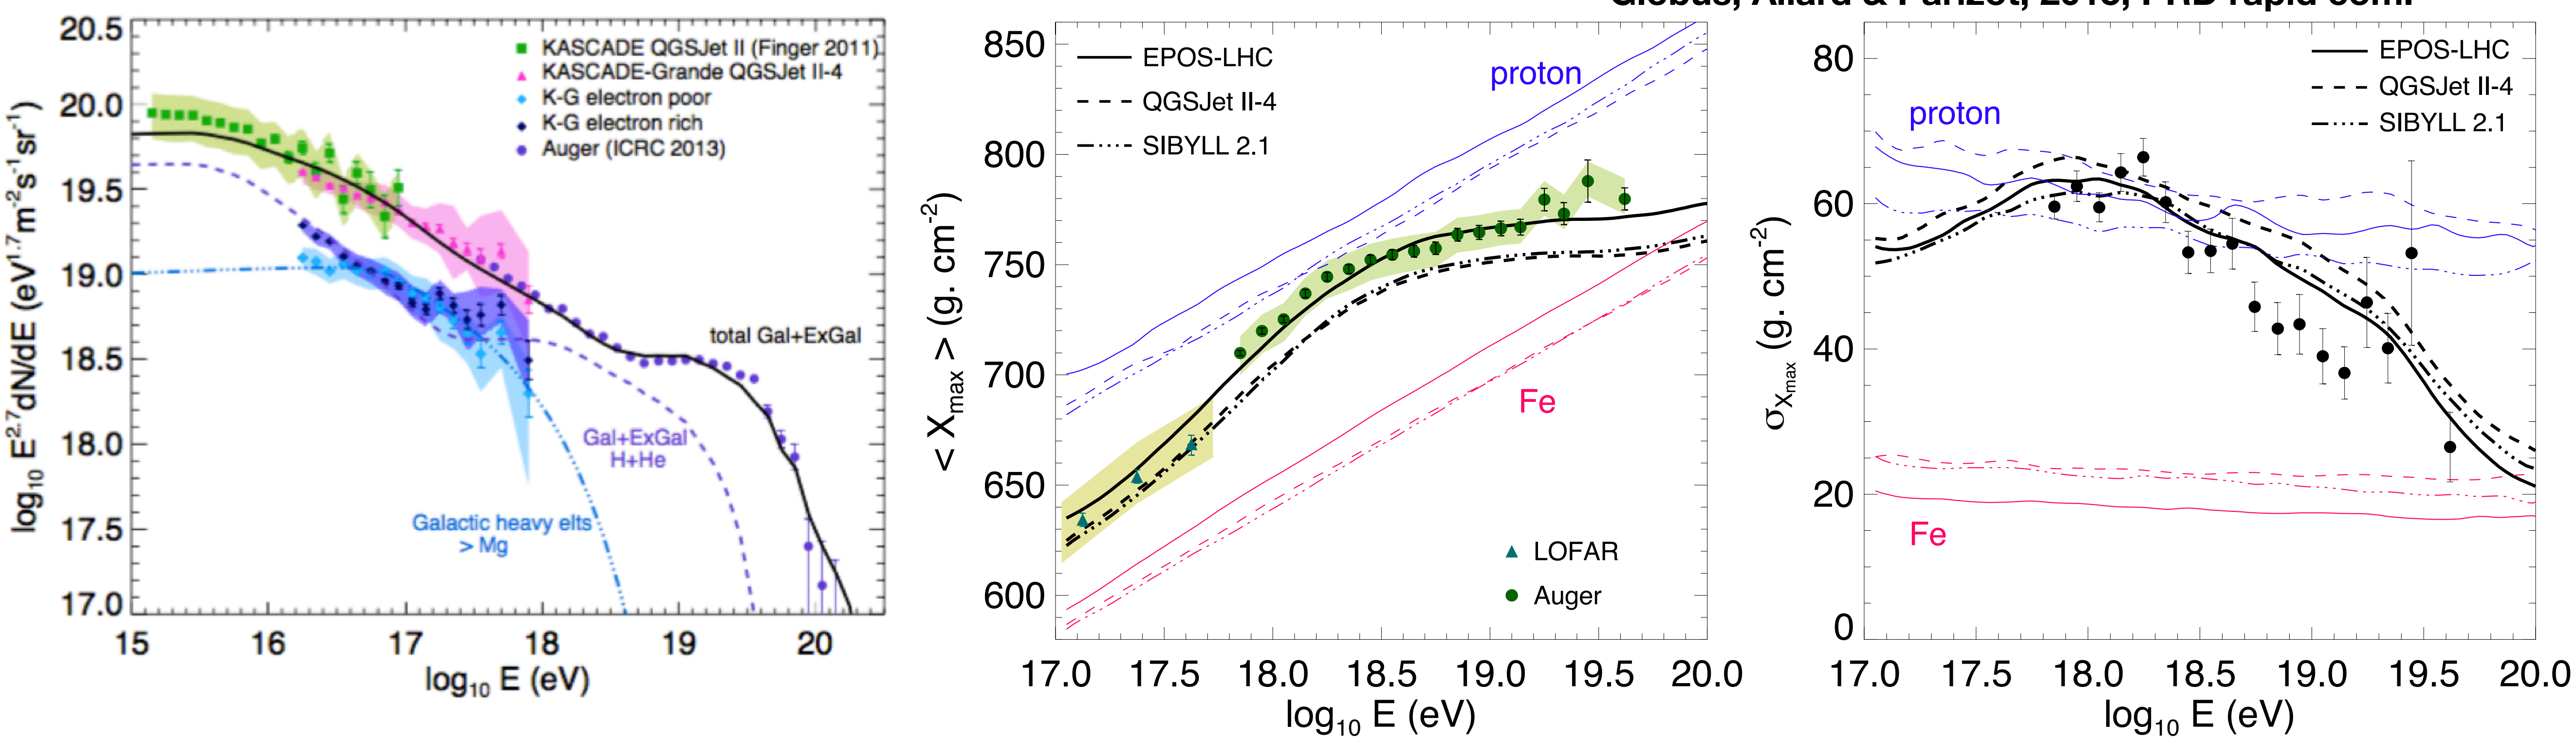
proton attenuation length as a function of the energy :
Strong decrease above ~5.10^{19} eV due to pion production with CMB photons
—> Horizon of UHE proton gets reduced above this energy
—> GZK cut-off for protons

nuclei mean free path for giant dipole resonance (photodisintegration) as a function of the Lorentz factor :
Strong decrease above $\Gamma \sim 5.10^9$ due to GDR interaction with CMB photons
—> Horizon of UHE nuclei get reduced an energy ~ $A \times 5.10^{18}$ eV
—> GZK cut-off for nuclei



Phenomenological model : implications for the GCR to EGCR transition

Globus, Allard & Parizot, 2015, PRD rapid com.

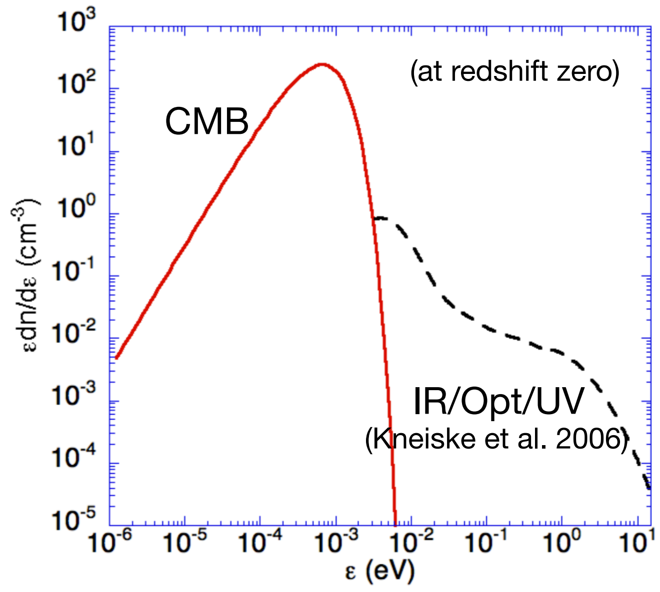


Extragalactic model coupled to a simple description of the Galactic component
(abundances obtained from balloon and satellite measurements, broken power laws assumed to reproduce the knee of the different species at energies proportional to Z)

- Fair reproduction of the light ankle and heavy galactic component
- Good description of Auger composition observables when using the latest (LHC tested) hadronic models
- Good agreement with more recent Auger analyses (down to 10^{17} eV) and recent LOFAR (radio) measurements (as well as older HiRes MIA results)

Ultra-high-energy cosmic-rays, neutrinos and photons : the multi-messenger link

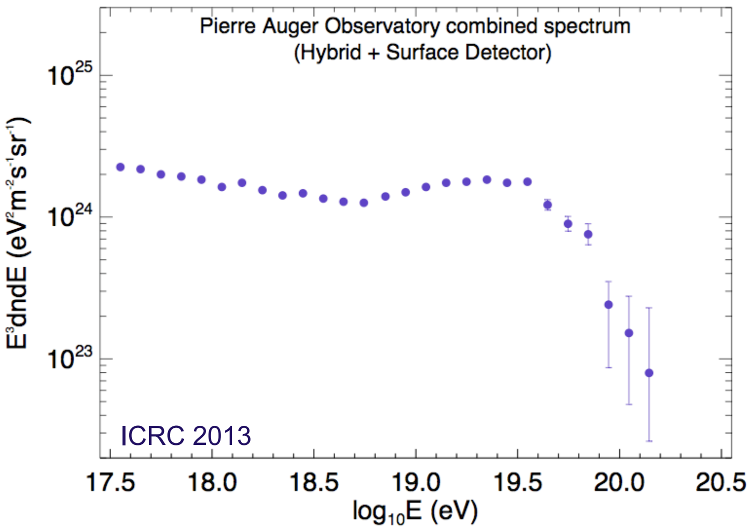
Extragalactic very-high and ultra-high-energy cosmic-rays produce secondary (cosmogenic) neutrinos and gamma-rays during their propagation interacting with the extragalactic background light (UV-optical-IR, CMB)



- pair production: $N+\gamma \rightarrow N+e^+/e^-$ ==> Threshold with CMB photons ~10^{18} eV per nucleon (at z=0)
- Pion and meson production :

$$\pi^0 \rightarrow 2\gamma$$
$$\pi^+ \rightarrow \mu^+ + \nu_\mu,\ \mu^+ \rightarrow \overline{\nu_\mu} + e^+ + \nu_e$$
$$\pi^- \rightarrow \mu^- + \overline{\nu_\mu},\ \mu^- \rightarrow \nu_\mu + e^- + \overline{\nu_e}$$

==> Threshold with CMB photons ~10^{20} eV per nucleon (at z=0)

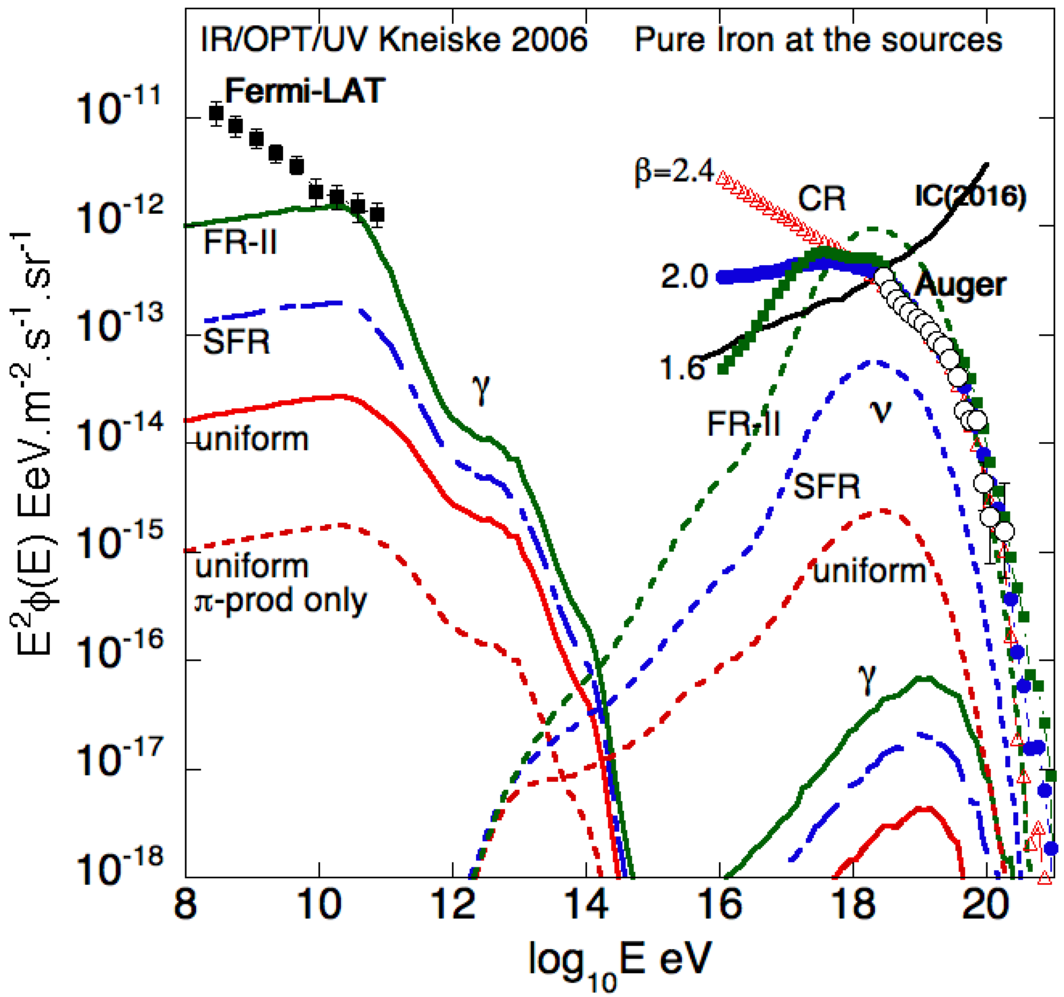


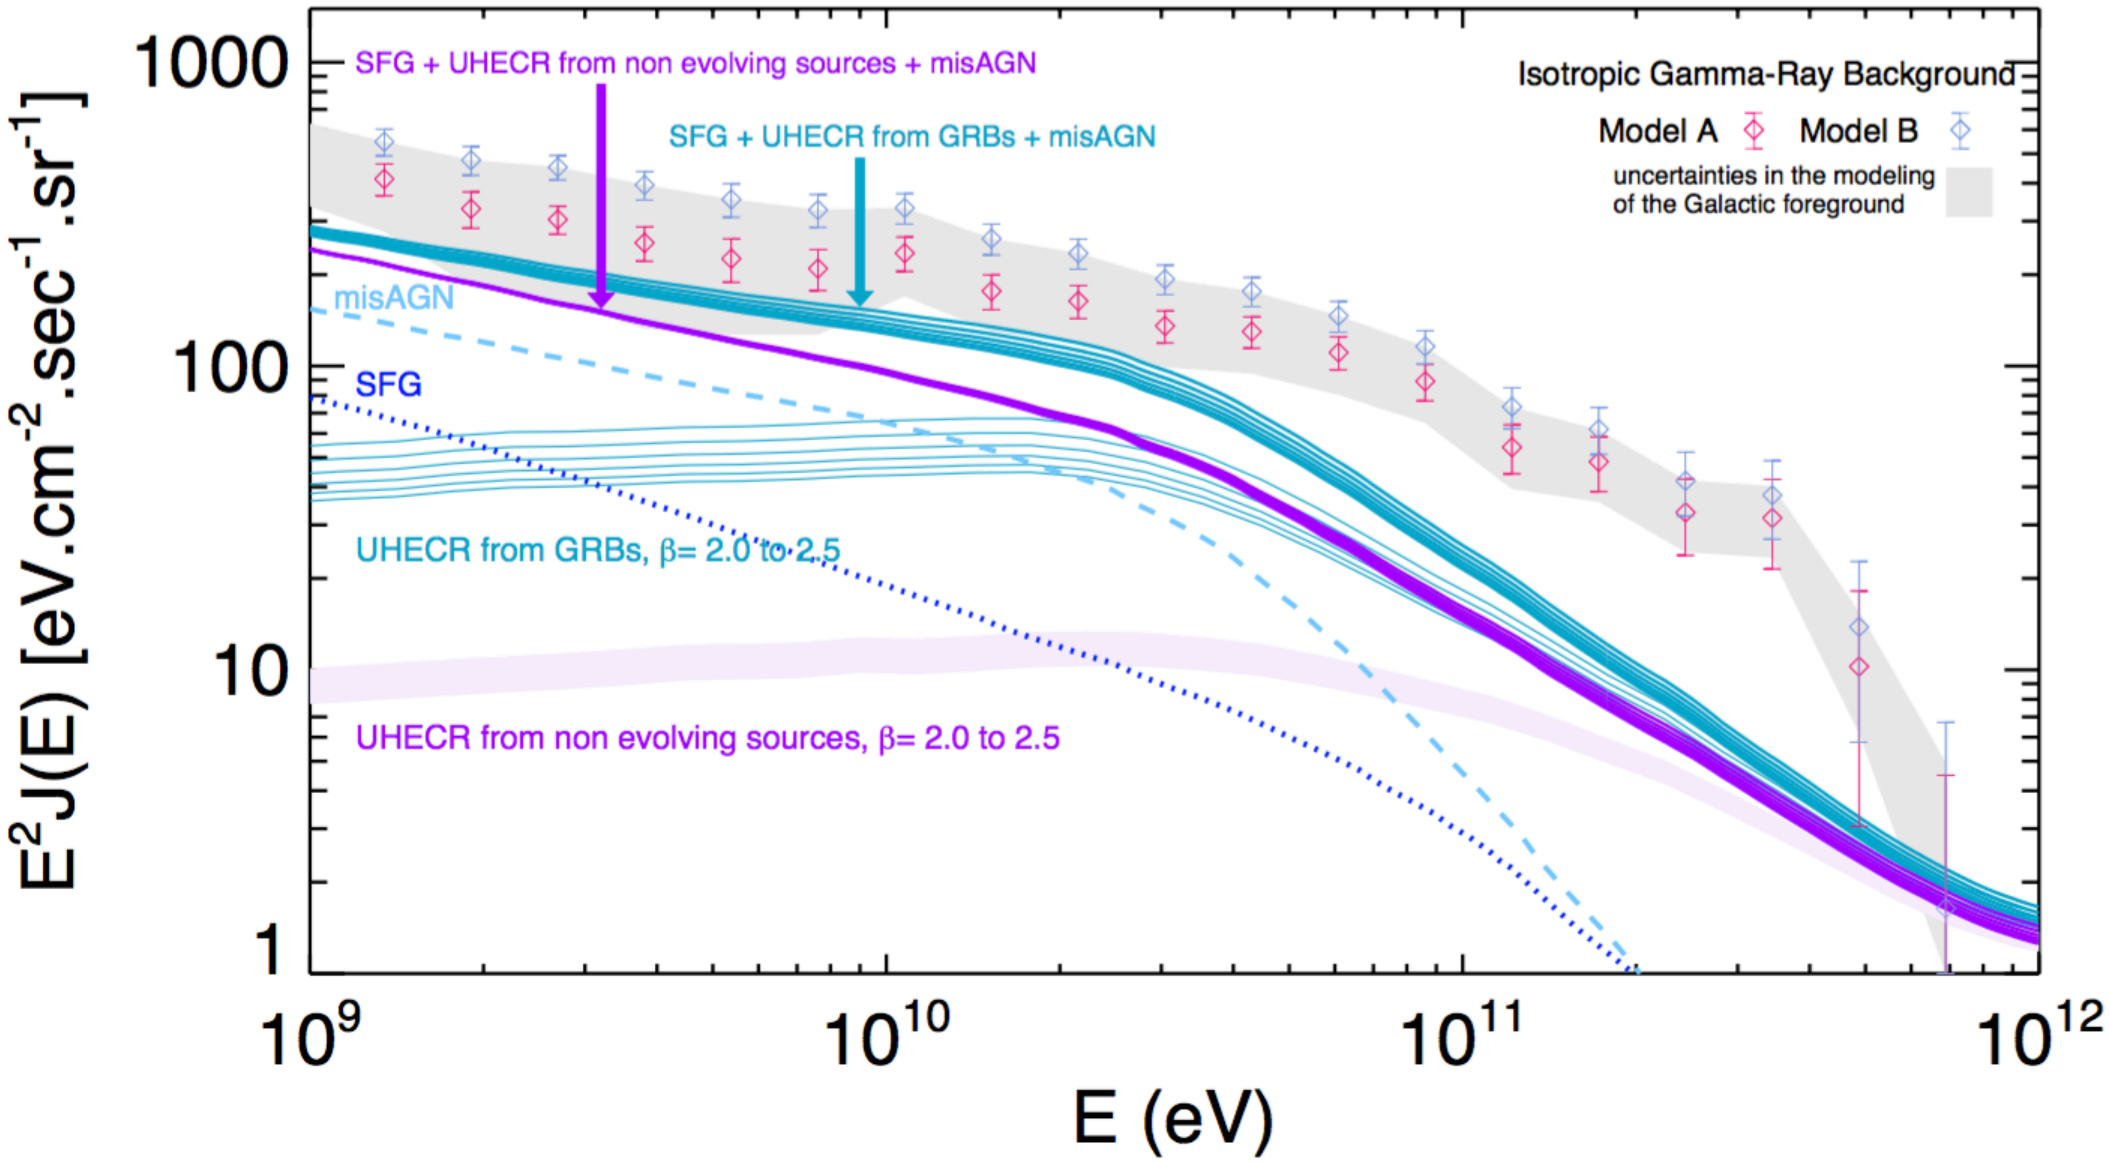
Large amount of interactions with CMB photons initiating electromagnetic cascades **guaranteed** (low energy threshold for e^+/e^-) even if the highest energy cosmic-ray are heavy

Large amount of interactions with CMB photons emitting neutrinos **not guaranteed** unless the highest energy cosmic-ray are light

Some examples of contraints brought by cosmogenic secondaries (III)

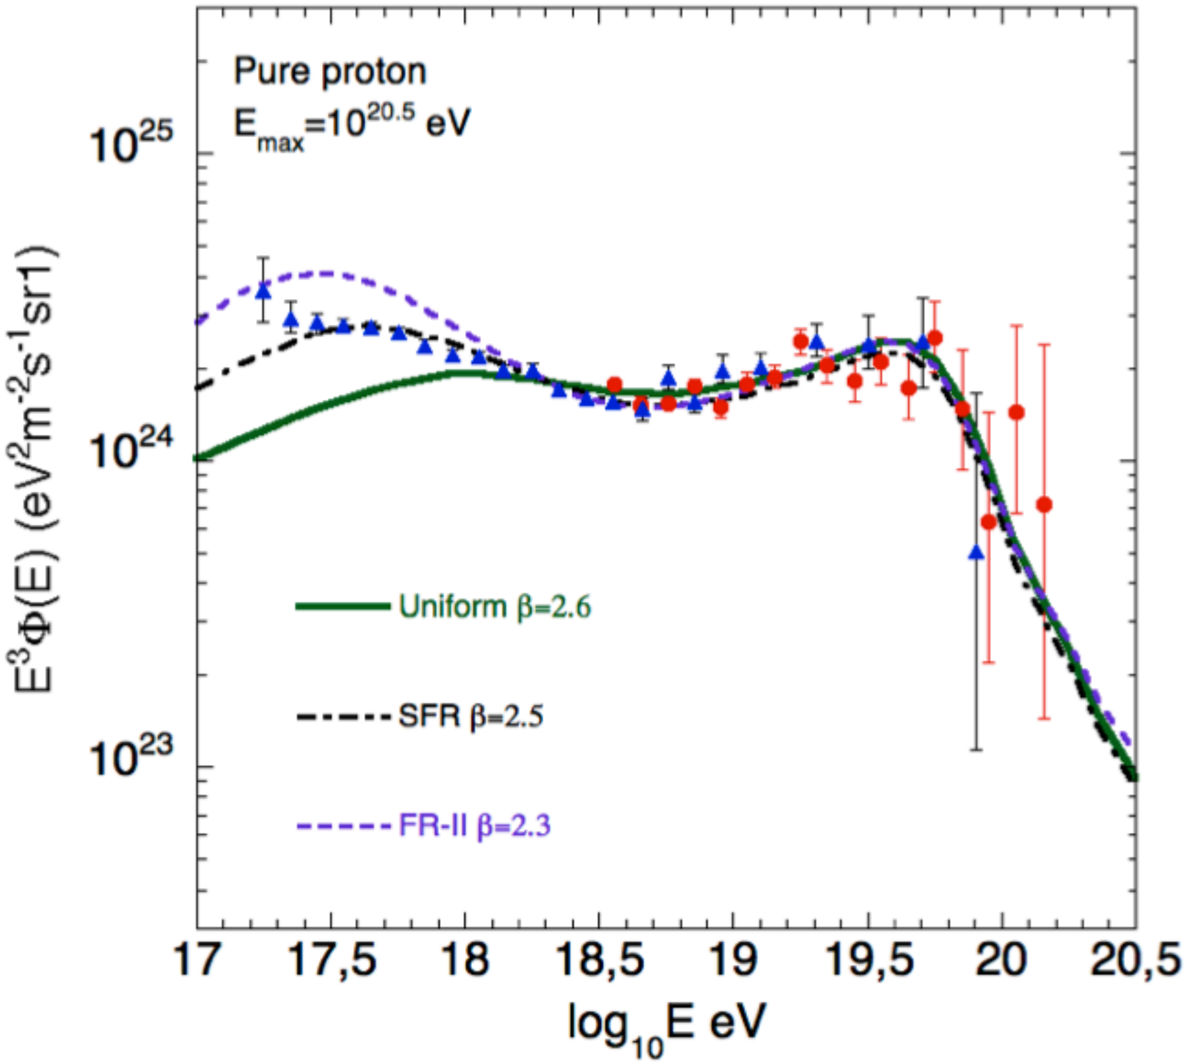
Assuming the maximum energy per nucleon is well above 10^{20} eV (what most people thought until ~2010) pure iron at the sources :



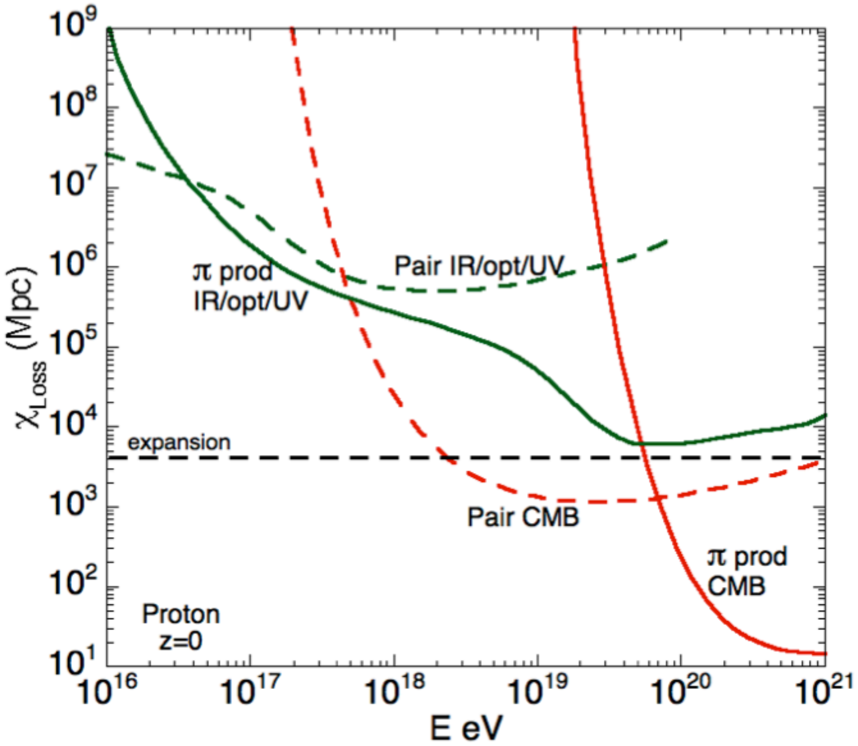


SFG + UHECR from non evolving sources + misAGN
SFG + UHECR from GRBs + misAGN
Isotropic Gamma-Ray Background
Model A
Model B
uncertainties in the modeling of the Galactic foreground
misAGN
SFG
UHECR from GRBs, β= 2.0 to 2.5
UHECR from non evolving sources, β= 2.0 to 2.5
E²J(E) [eV.cm⁻².sec⁻¹.sr⁻¹]
E (eV)

a special case : pure proton composition

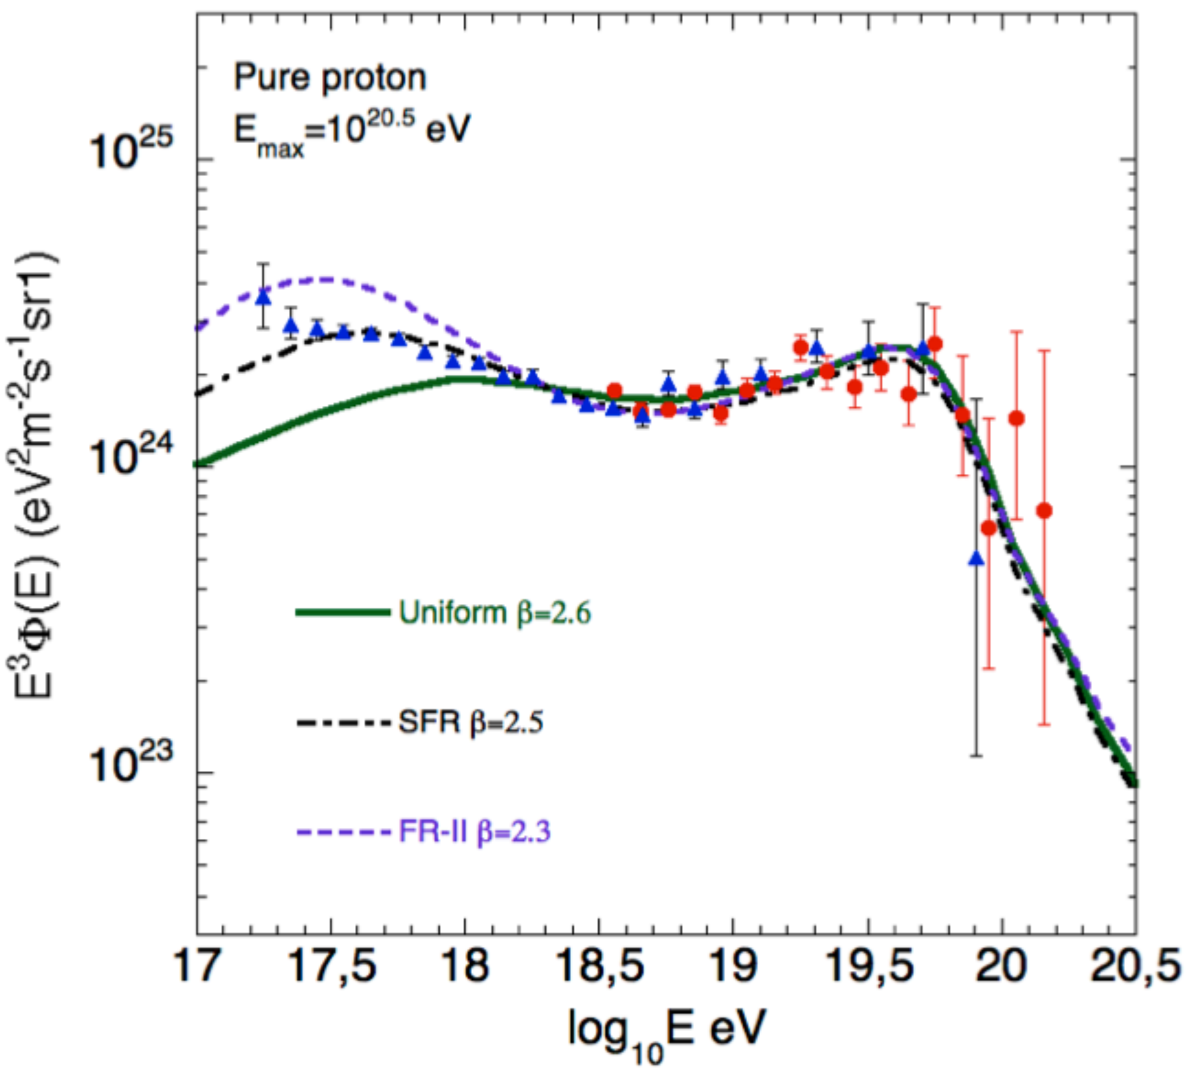


The ankle can be fitted by the extragalactic component itself : pair production dip->the ankle feature has nothing to do with the transition (model developed by Berezinsky et al., 2002-2007)



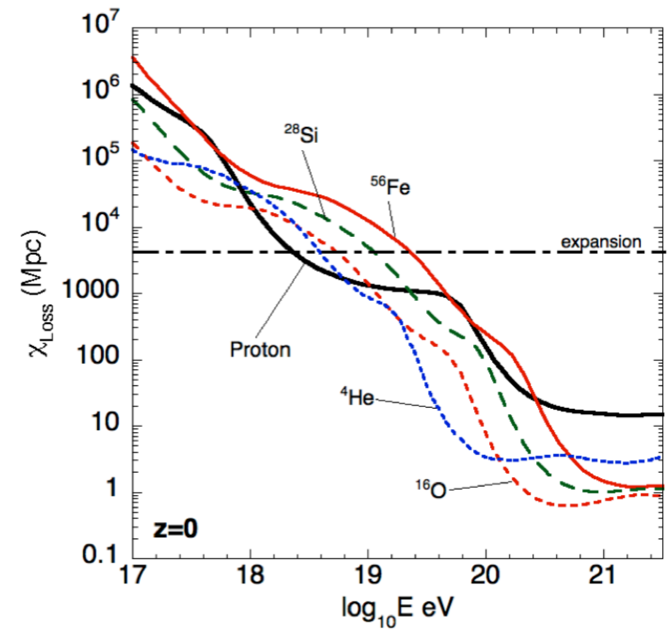
The existence of the pair production dip is due to the energy evolution of the proton attenuation length

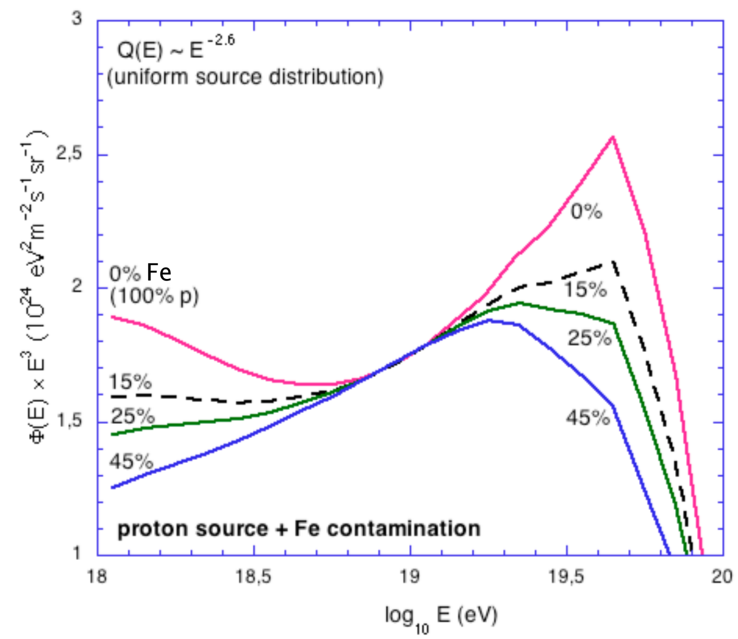
a special case : pure proton composition



The ankle can be fitted by the extragalactic component itself : pair production dip->the ankle feature has nothing to do with the transition (model developed by Berezinsky et al., 2002-2007)

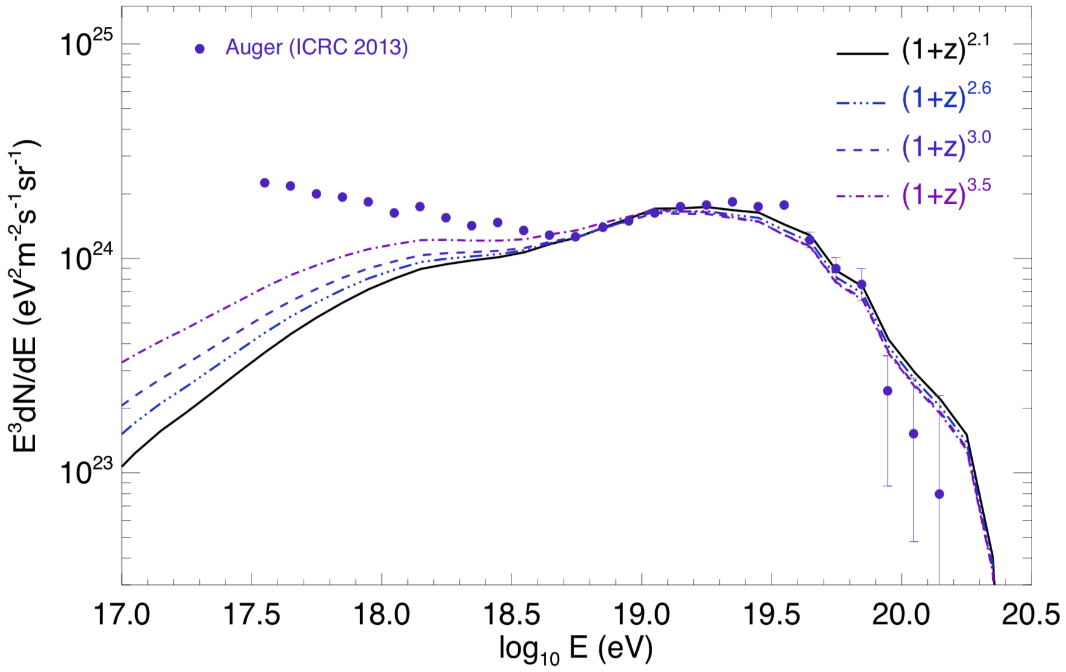
BUT





The attenuation length evolution is different for nuclei

Phenomenological model : implications for the GCR to EGCR transition



To match the KG light component estimate with post-LHC hadronic models, a boost of the predicted proton component is need

It can be done in two ways :

- Choose a stronger cosmological evolution
- Assume a softer spectrum for the protons

➡ in both cases these modifications result in larger predicted cosmogonic photon fluxes

These fluxes however remain compatible with Fermi 2010 IGRB

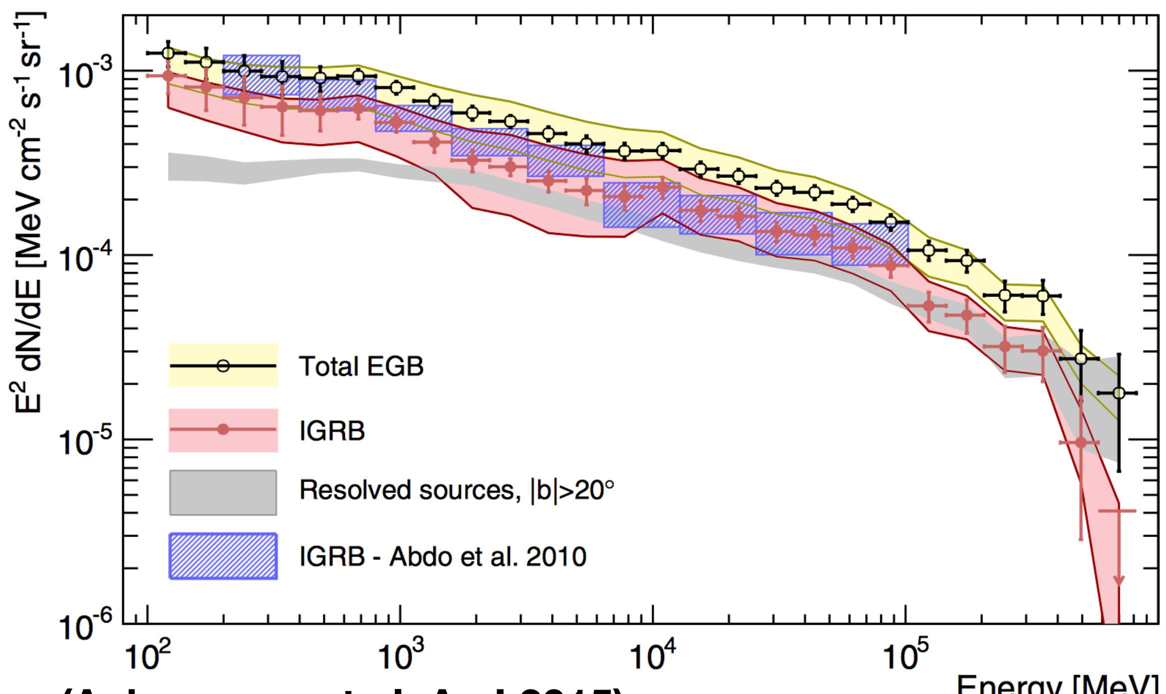
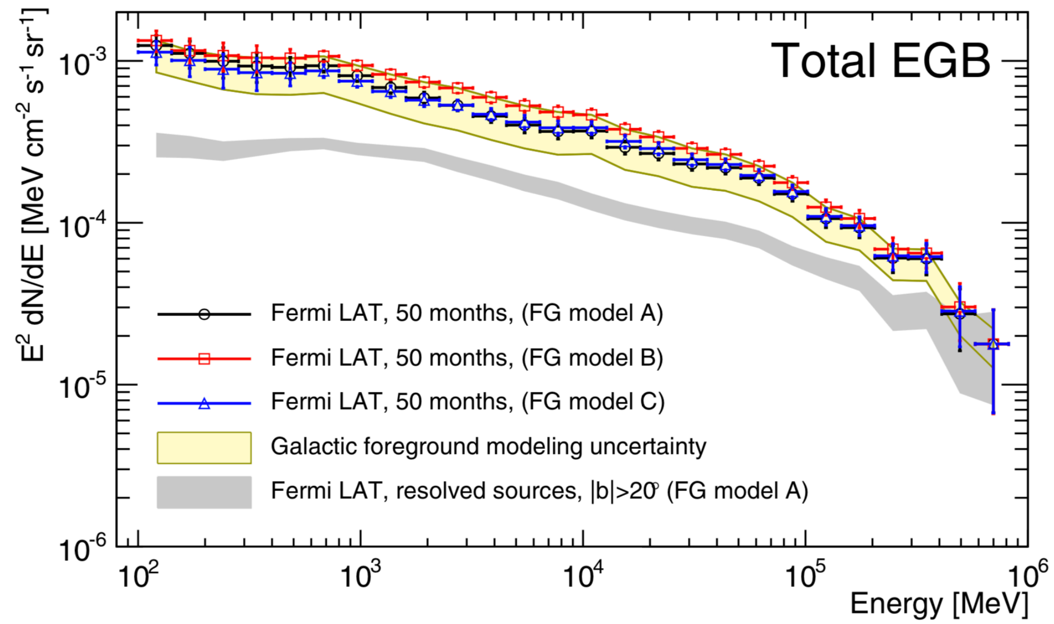
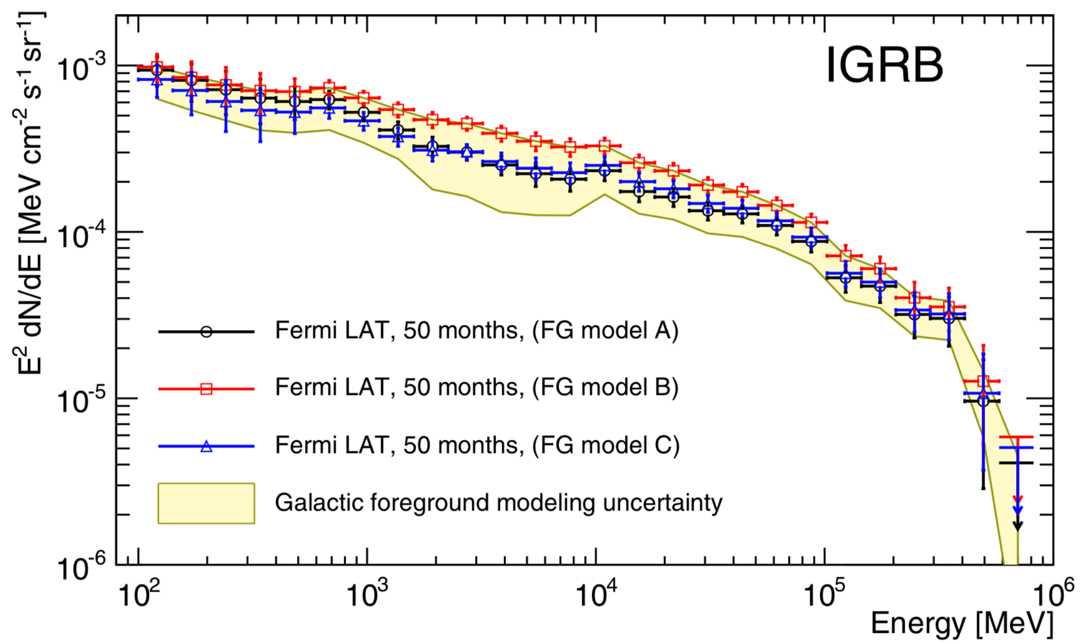
Recent Fermi measurements : extended energy range and galactic foreground intensity

Fermi recently released an updated estimate of the extragalactic γ-ray background for both the resolved and unresolved components
➡Larger statistics and extended energy range



(Ackermann et al. ApJ 2015)



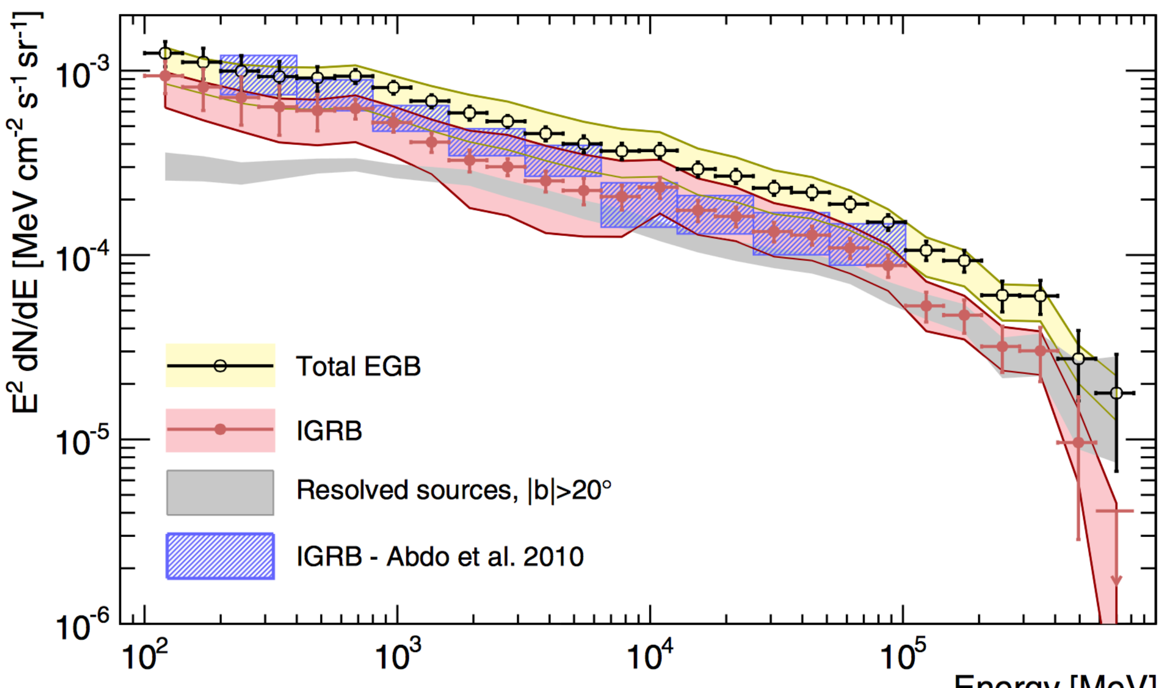


Better account of the uncertainties on the modelling of the galactic foreground
➡3 different estimates (models A, B and C) corresponding to three equally realistic theoretical modelings of the galactic foreground

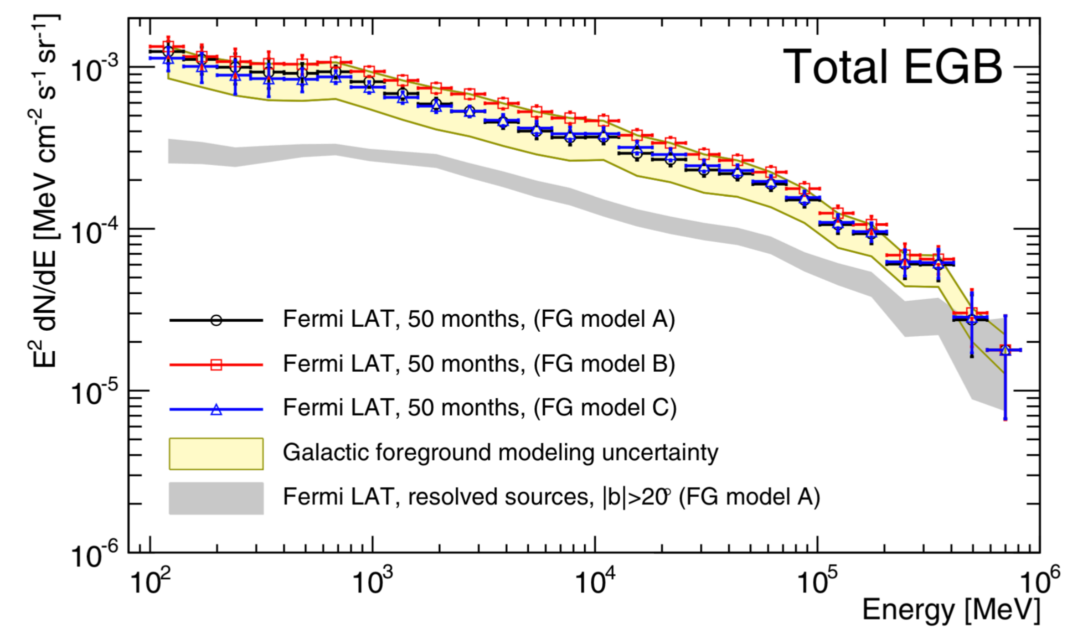
Recent Fermi measurements : extended energy range and galactic foreground intensity

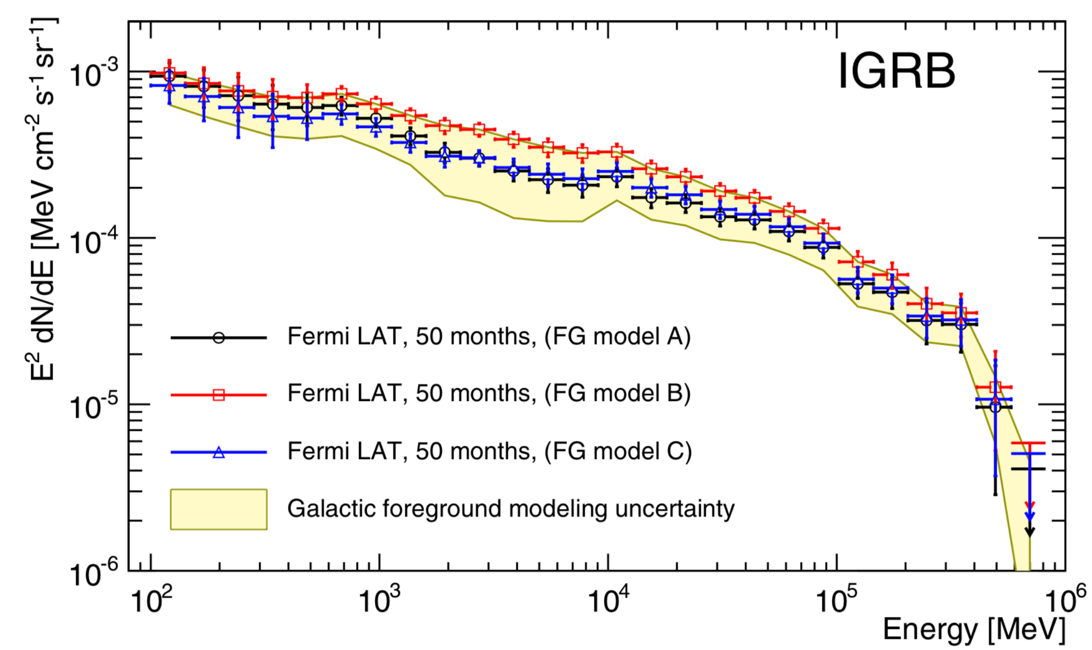
Fermi recently released an updated estimate of the extragalactic γ-ray background for both the resolved and unresolved components

➡Larger statistics and extended energy range



(Ackermann et al. ApJ 2015)





NB : The total extragalactic γ-ray background is made of several contributions :

- resolved point sources (very large majority of Blazars)
- unresolved point sources (mostly blazars, misaligned AGNs and star forming galaxies (contribute also to the IGRB)
- truly diffuse processes (UHECR for sure, possibly DM)

➡ **estimating the different contributions would help constraining that of UHECRs**

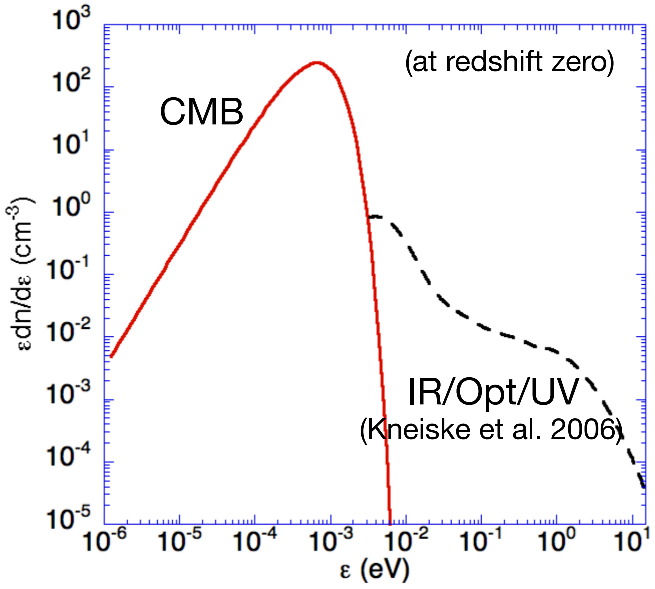
Ultra-high-energy cosmic-rays (UHECR), neutrinos and photons : the multi-messenger link

UHECR are strongly suspected to be of extragalactic origin

Extragalactic very-high and ultra-high-energy cosmic-rays produce secondary (cosmogenic) neutrinos and gamma-rays during their propagation interacting with the extragalactic background light (UV-optical-IR, CMB)

- pair production: $N+\gamma \rightarrow N+e^+/e^-$ ==> *secondary* $e^{+/-}$
- Pion and meson production :

$$\pi^0 \rightarrow 2\gamma$$
$$\pi^+ \rightarrow \mu^+ + \nu_\mu,\ \mu^+ \rightarrow \overline{\nu_\mu} + e^+ + \nu_e \text{ ==> } secondary\ e^{+/-}, \gamma\ and\ \nu$$
$$\pi^- \rightarrow \mu^- + \overline{\nu_\mu},\ \mu^- \rightarrow \nu_\mu + e^- + \overline{\nu_e}$$



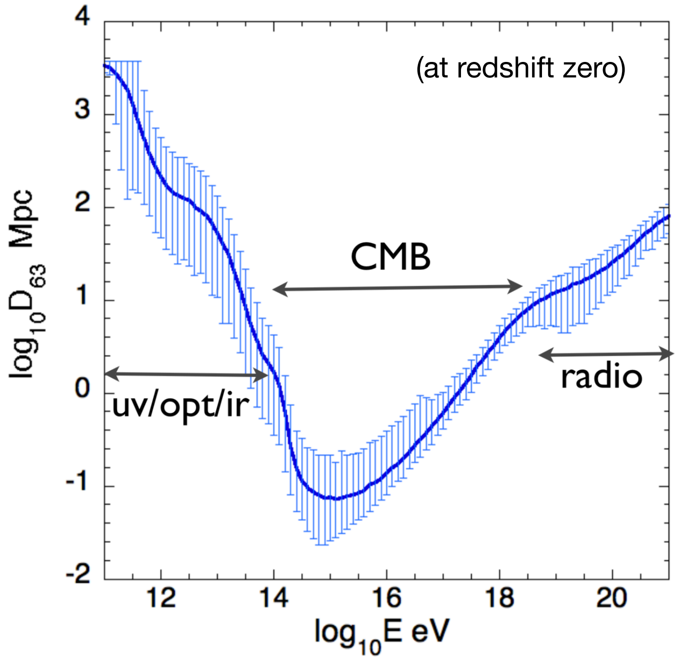
νs only suffer from adiabatic losses while propagating in the EGM

e^+/e^- and γ further cascade by interacting with the EBL :

$e+\gamma_{EBL} \rightarrow e'+\gamma$ ICS

$\gamma+\gamma_{EBL} \rightarrow e^+ + e^-$ pair production

➡ the universe is opaque to high-energy γs (pile-up at sub-TeV energies)

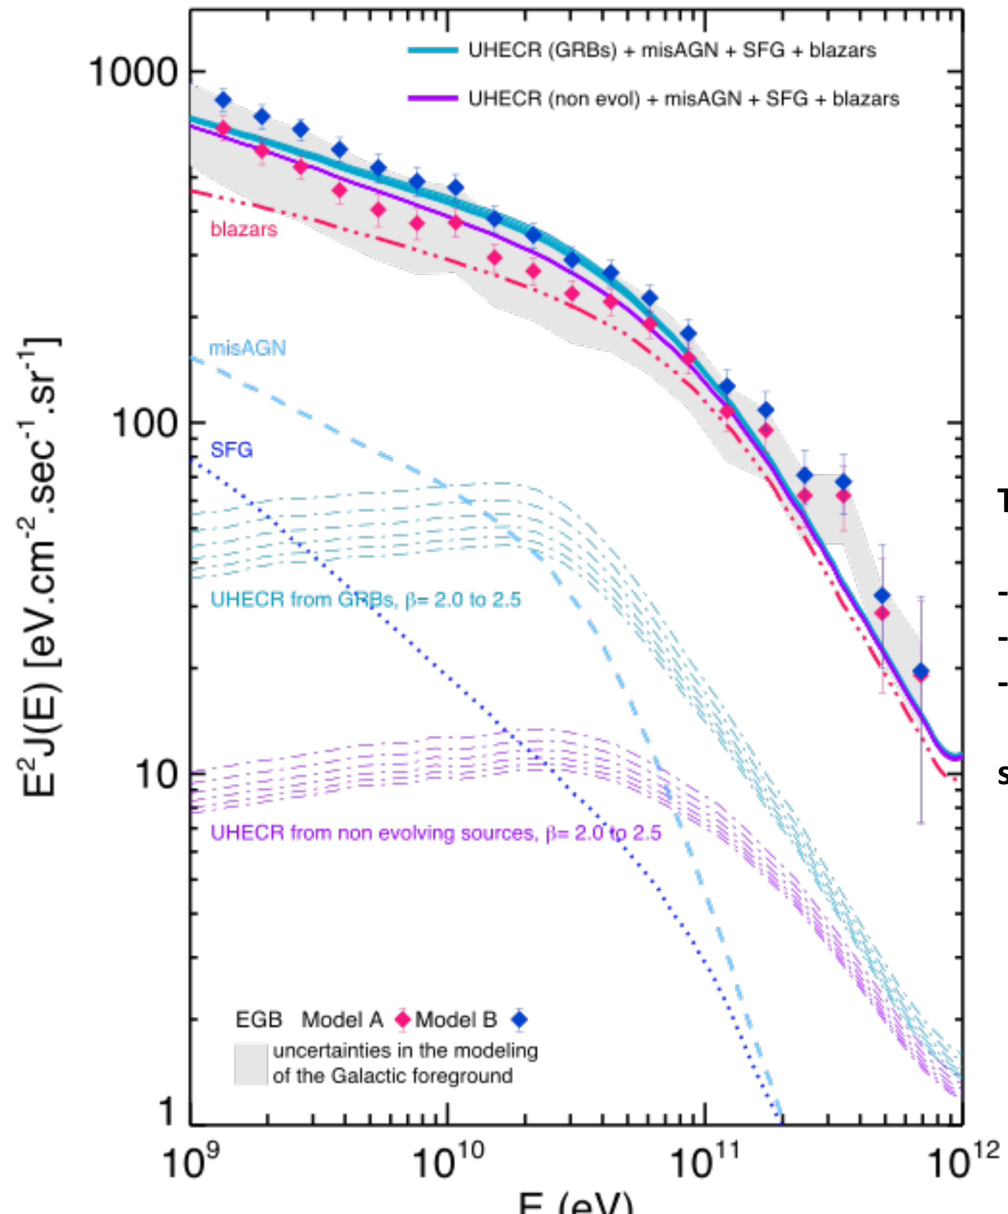


Diffuse UHECR (E>10^{17} eV) flux

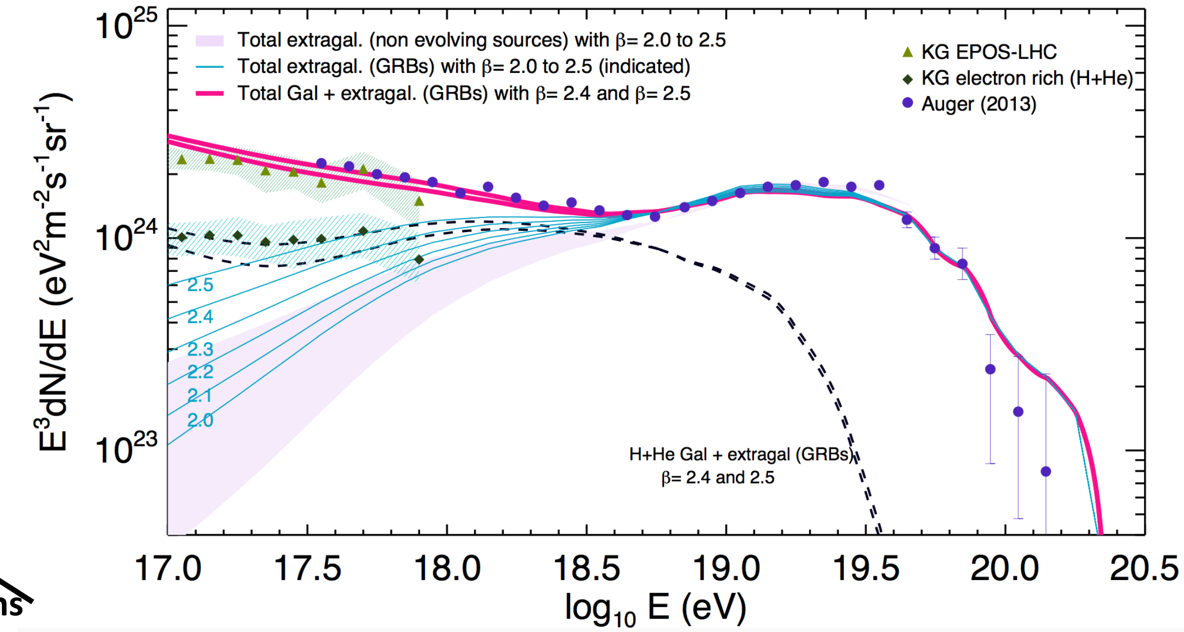
➡ diffuse ν flux in the PeV-EeV range

➡ diffuse γ-ray flux in the GeV-TeV range

Constraints on UHECR source models (I)



Globus et al., 2017, ApJL



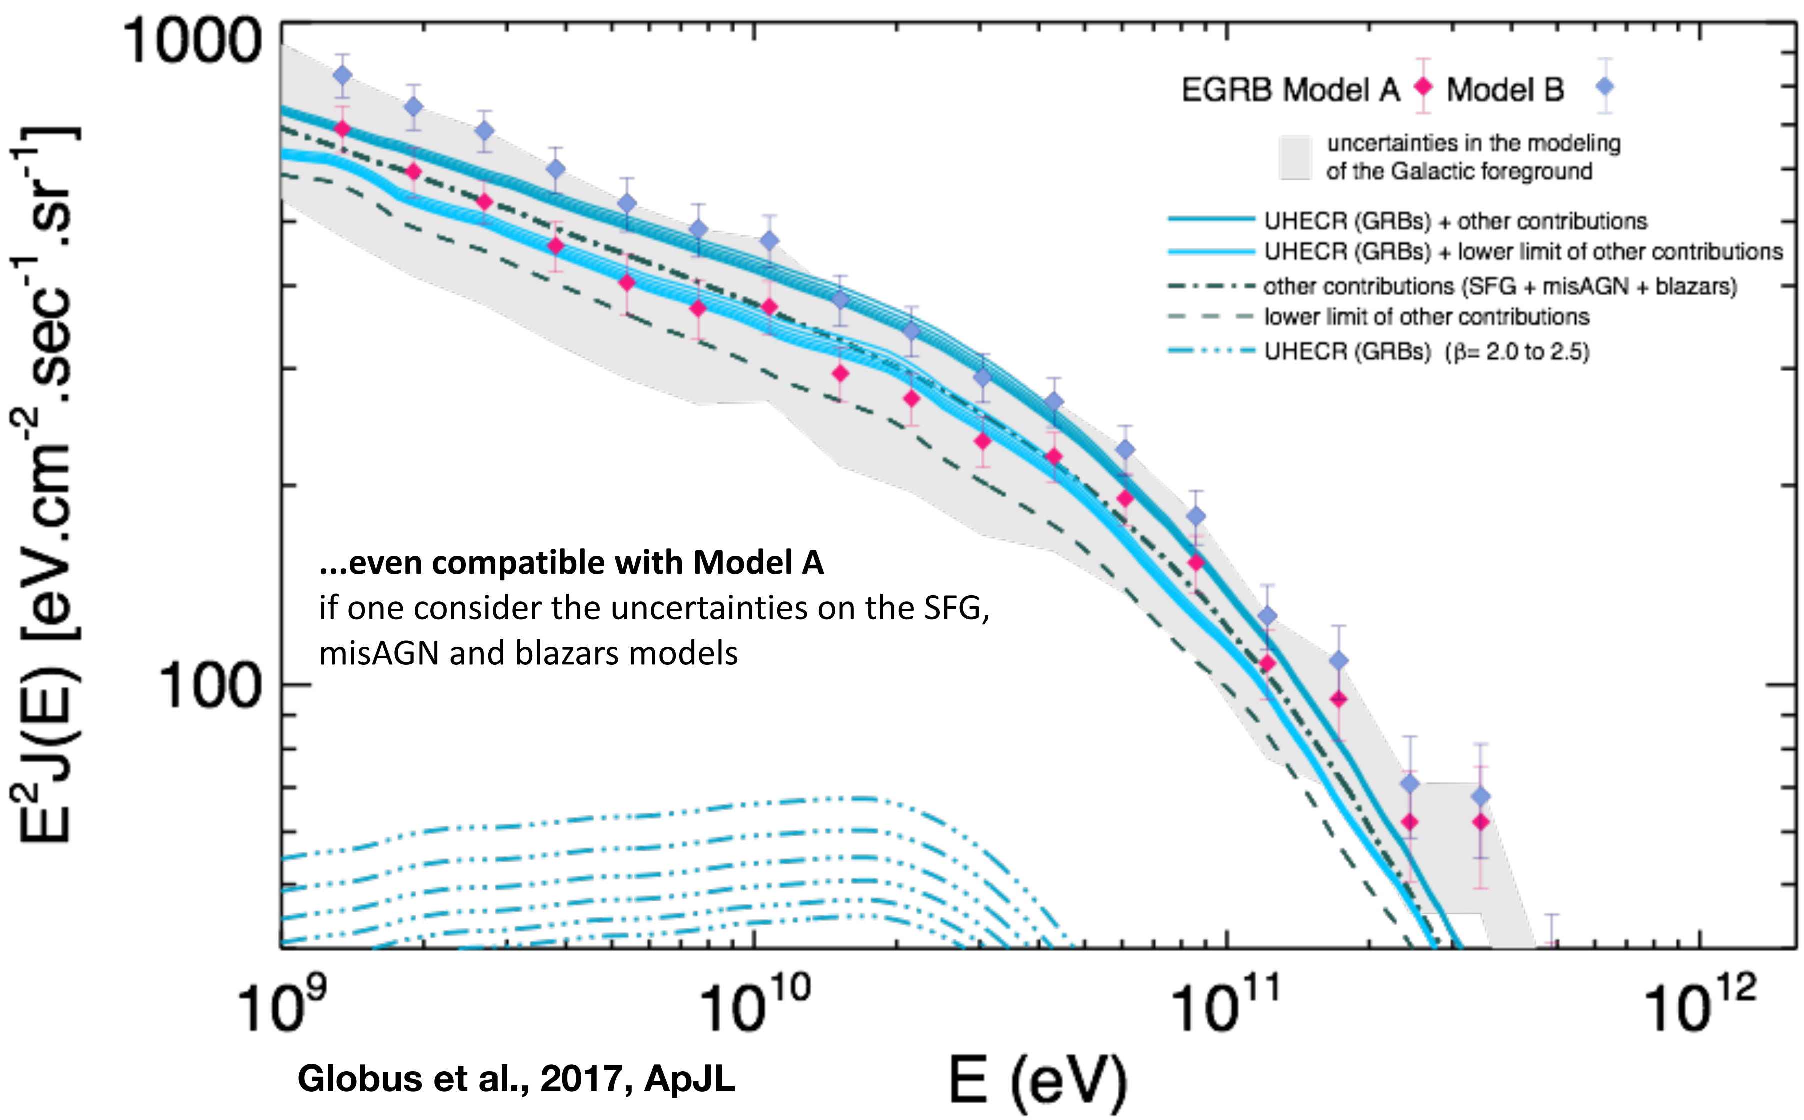
Total of all contributions

- **SFGs (**Ackermann et al. 2012, Fermi Collab.**)**
- **misaligned AGNs (**Inoue 2011**)**
- **blazars (**Ajello et al. 2015**)**

seems compatible with Model B…

The uncertainty on the total EGRB is a major aspect of the discussion

Constraints on UHECR source models (II)



Globus et al., 2017, ApJL

The uncertainty on the amplitude of the different contributions is also a major aspect of the discussion

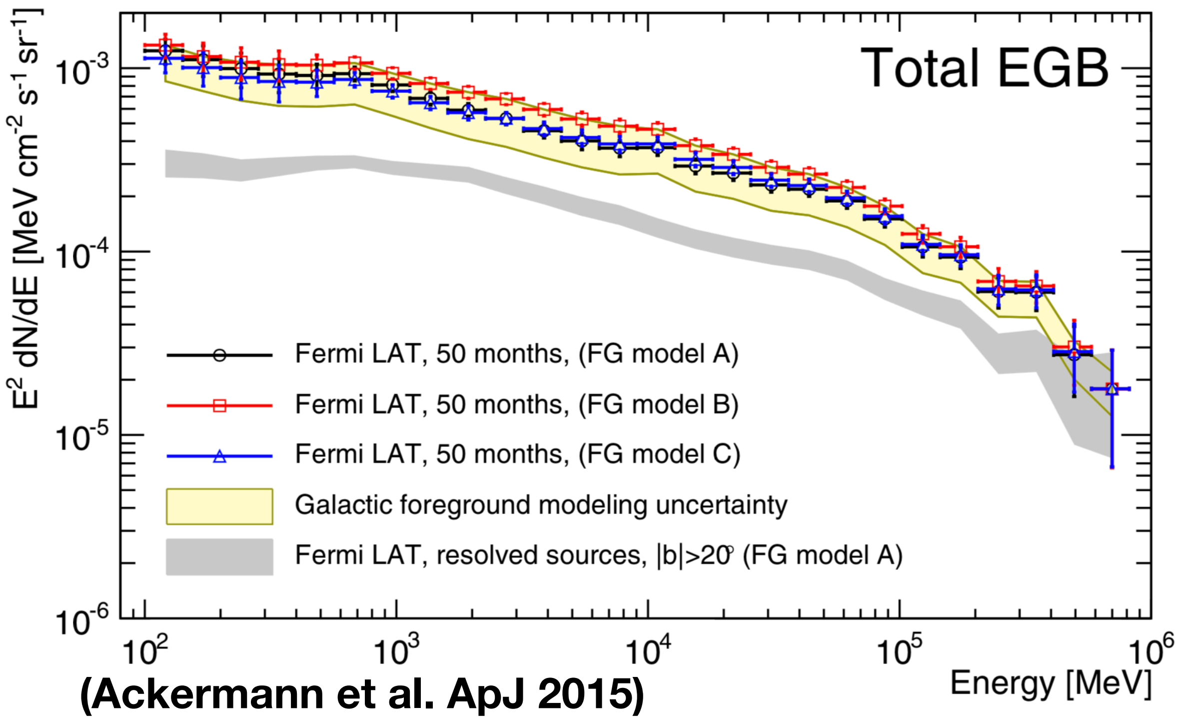
(considering the mean values of the SFG+misAGN models)

Cosmogenic γ-rays always represent a relatively small fraction of the EGRB even for GRB or SFR evolution and model A

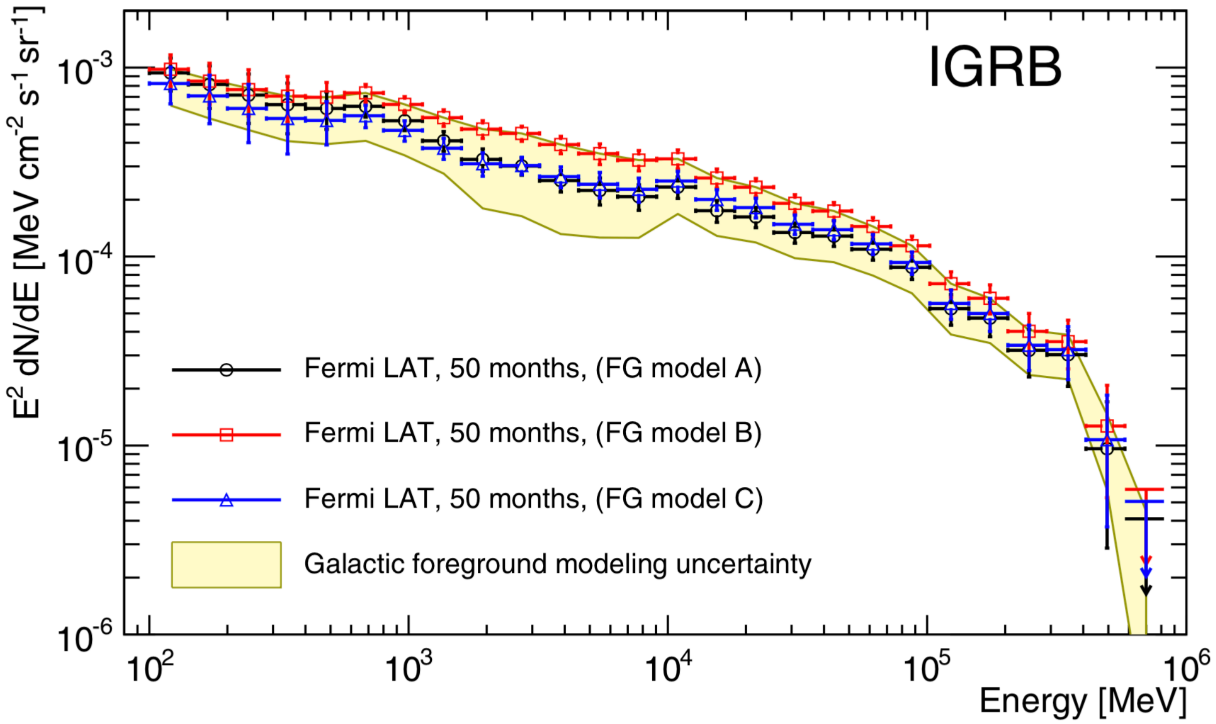
Can be comfortably added to the other contribution in the case of model B

Recent Fermi estimates of the extragalactic γ-ray background

Fermi recently released an updated estimate of the extragalactic γ-ray background for both the resolved and unresolved components



(Ackermann et al. ApJ 2015)



Account of the uncertainties on the modelling of the galactic foreground
➡3 different estimates (models A, B and C) corresponding to three equally realistic theoretical modelings of the galactic foreground

NB : The total extragalactic γ-ray background is made of several contributions :

- resolved point sources (very large majority of Blazars)
- unresolved point sources (mostly blazars, misaligned AGNs and star forming galaxies (contribute also to the IGRB)
- truly diffuse processes (UHECR for sure, possibly DM)

➡ **estimating the different contributions would help constraining that of UHECRs**

Recent Fermi measurements : estimates of point sources contribution to the γ-ray background

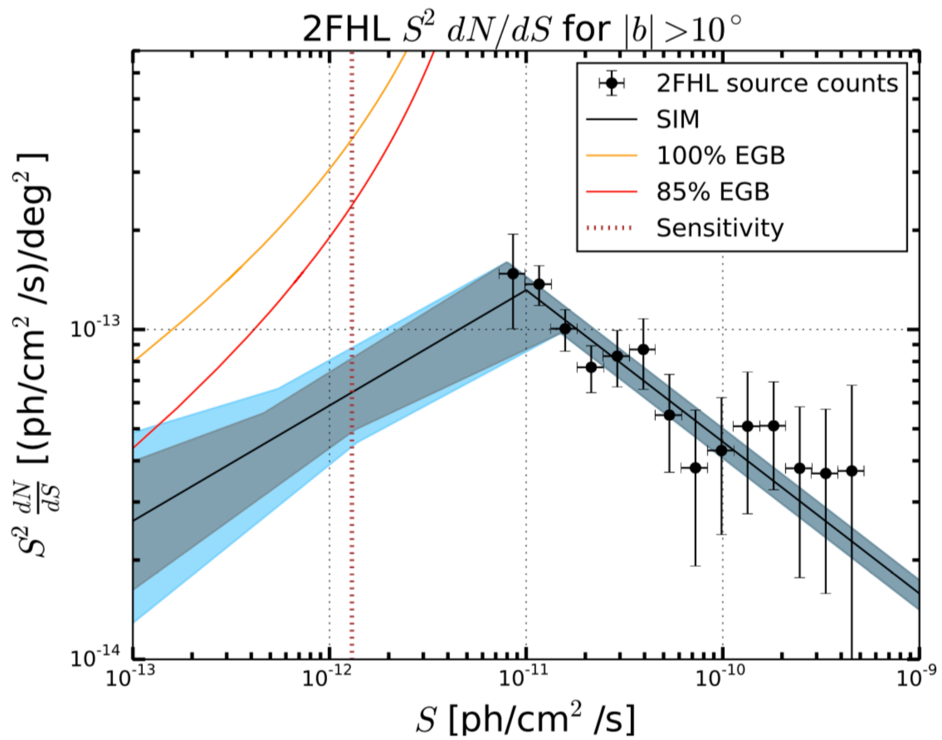
Different estimates of the contribution of point sources (resolved and unresolved) to the total γ-ray background were proposed

2 recent studies:

- Ackermann et al. , PRL, 2016 (**A16**)
- Zechlin et al., ApJ, 2016 (**Z16**)

(based on a method proposed in Malyshev & Hogg 2011)

	(Z16)					(A16)
Energy bands (in GeV)	① 1.04–1.99	② 1.99–5.0	③ 5.0–10.4	④ 10.4–50	⑤ 50–171	⑥ 50–2000
F_{PS} ($\times 10^{-9}\,\mathrm{cm^{-2}\cdot s^{-1}\cdot sr^{-1}}$)	250^{+20}_{-40}	124^{+7}_{-25}	27^{+8}_{-3}	14^{+6}_{-1}	$1.7^{+1.1}_{-0.4}$	$2.07^{+0.40}_{-0.34}$
F_{PS}/F_{EGB} (% Model B)	68^{+5}_{-10}	63^{+4}_{-13}	52^{+15}_{-6}	51^{+22}_{-4}	65^{+41}_{-15}	71^{+13}_{-12}



(Ackermann et al., PRL 2016)

The contribution of the resolved point sources is estimated for fluxes well below the point source detection limits using the so-called "photon fluctuations analysis"

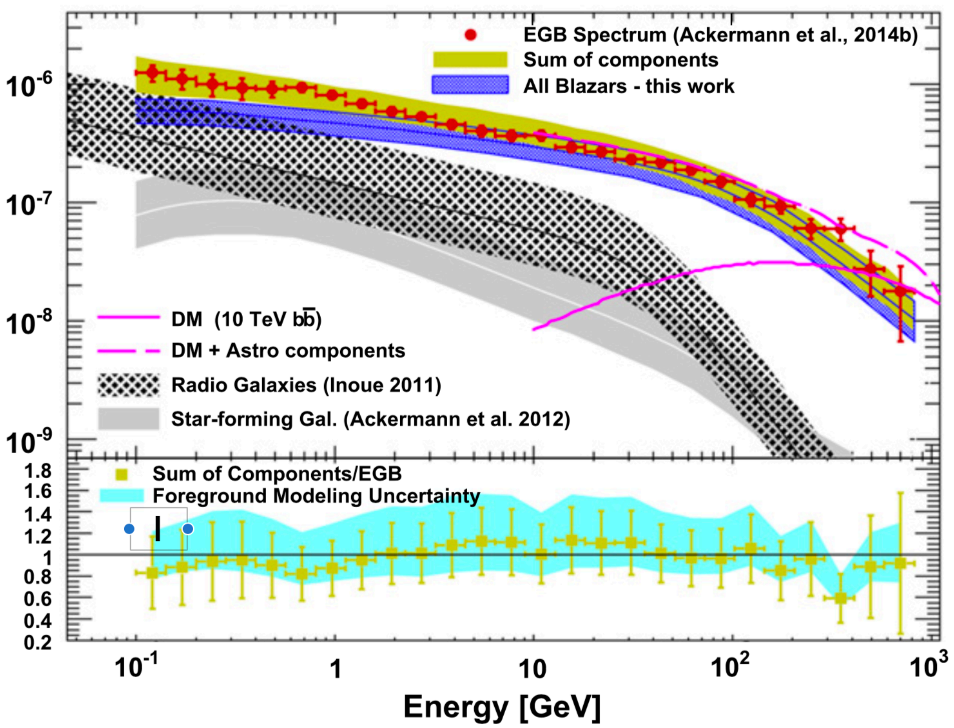
➡ fluxes due to (resolved and unresolved) point sources are estimated in each energy bands

➡ fractional contributions to the total γ-ray background are deduced in each bands

➡ **Large fractions deduced**

NB : these estimates are probably including blazar point sources and might not include the contributions of weak sources (but numerous) such as star-forming galaxies and misaligned AGNs

Recent Fermi measurements : estimates of point sources contribution to the γ-ray background



Ajello et al., ApJ, 2015

	(Z16)					(A16)
Energy bands (in GeV)	① 1.04–1.99	② 1.99–5.0	③ 5.0–10.4	④ 10.4–50	⑤ 50–171	⑥ 50–2000
$F_{\rm PS}$ ($\times 10^{-9}\,{\rm cm^{-2}\cdot s^{-1}\cdot sr^{-1}}$)	250^{+20}_{-40}	124^{+7}_{-25}	27^{+8}_{-3}	14^{+6}_{-1}	$1.7^{+1.1}_{-0.4}$	$2.07^{+0.40}_{-0.34}$
$F_{\rm PS}/F_{\rm EGB}$ (% Model B)	68^{+5}_{-10}	63^{+4}_{-13}	52^{+15}_{-6}	51^{+22}_{-4}	65^{+41}_{-15}	71^{+13}_{-12}
$F_{\rm SFG+misAGN}$ ($\times 10^{-9}\,{\rm cm^{-2}\cdot s^{-1}\cdot sr^{-1}}$)	94^{+100}_{-36}	44^{+49}_{-18}	10^{+12}_{-4}	$4.5^{+5.4}_{-1.9}$	$0.17^{+0.18}_{-0.07}$	$0.18^{+0.19}_{-0.07}$
$F_{\rm SFG+misAGN}/F_{\rm EGB}$ (% Model B)	25^{+27}_{-10}	23^{+25}_{-9}	20^{+23}_{-8}	16^{+20}_{-7}	6^{+7}_{-3}	6^{+6}_{-2}

Using theoretical estimates of the contribution (almost exclusively unresolved) of SFG and misaligned AGNs one can add their contributions to that attributed to blazars in Z16 and A16

The contribution of UHECR must added to those of astrophysical sources to check whether or not a given astrophysical model is viable.
