

The Dark Energy Survey

Cosmology from Weak Lensing and Galaxy Clustering

David Sánchez-Cid

Postdoctoral Research Associate, University of Zurich

The LCDM Model

Our current Standard of Cosmology

A flat Universe with **Dark Energy** (as a cosmological constant, Λ) + **Cold Dark Matter**.

Based on **General Relativity**.

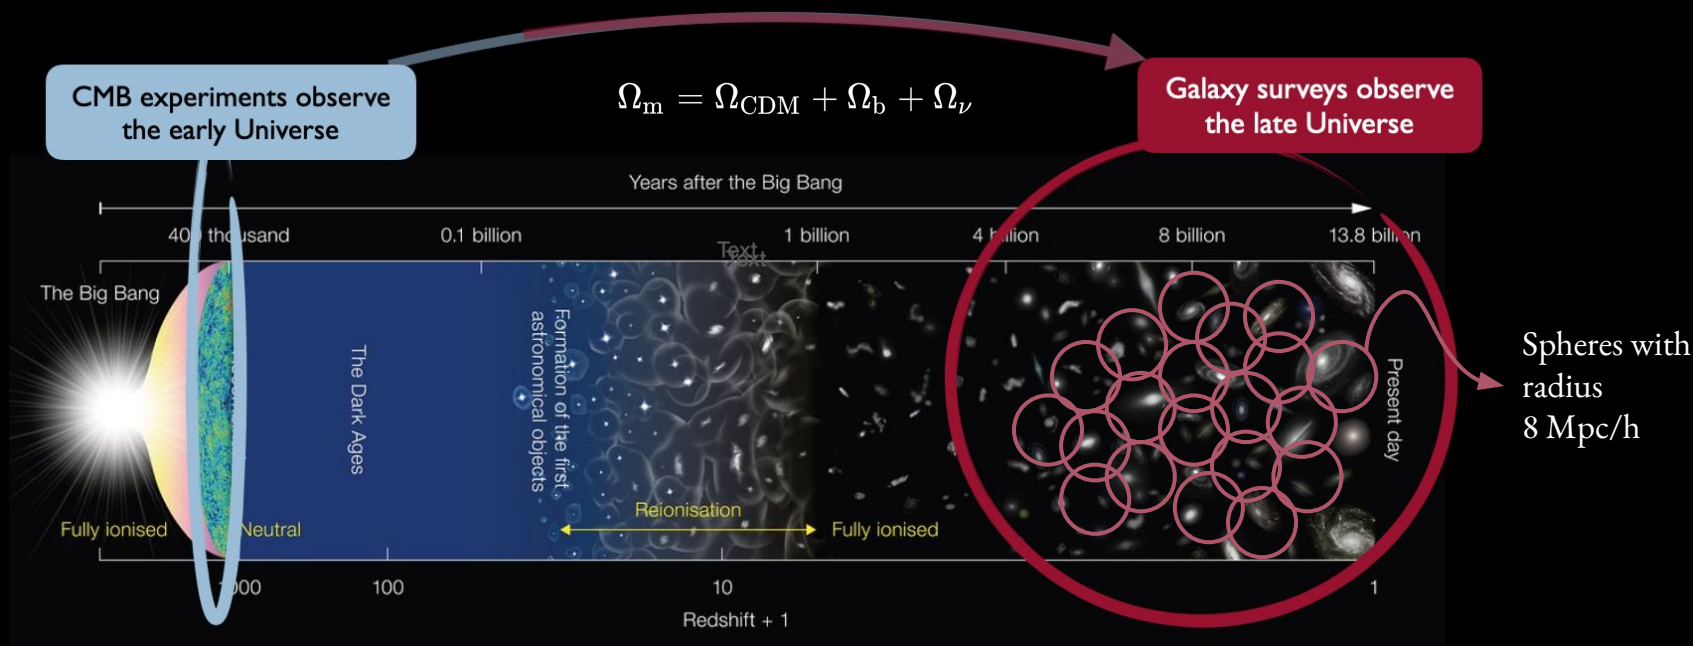

Became the standard model after observations of **Type Ia supernovae** and the **Cosmic Microwave Background**.

From the Early Universe to today

Growth of structure

Gravitational collapse sourced by Ω_m vs. expansion due to the dark energy

A_s : Amplitude of primordial scalar density fluctuations.

Image credit: NAOJ

σ_8 : Amplitude of mass fluctuations today.

Beyond Dark Energy

Key Open Questions in Cosmology

What is **Dark Matter**?

What is the **mass of the neutrinos**?

Hints of **dynamical Dark Energy**?

Why is there an **S₈ tension**?

KIDS+DES cosmic shear

Why is there an **H₀ tension**?

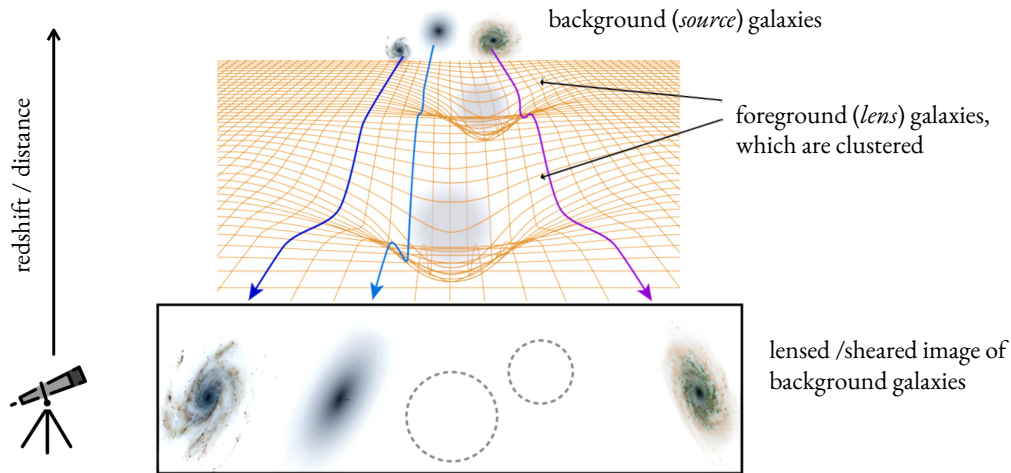

Riess et al.

Into the era of precision cosmology with galaxy surveys

Observed galaxies used as:

- (*biased*) **tracer** of the dark matter large-scale structure,
- **background light**, to statistically probe the matter distribution.

Weak gravitational lensing

Tracing the Large-Scale Structure

Credits to Jamie McCullough

Light from distant galaxies is **weakly distorted** by mass along the line-of-sight

Distortion changes galaxy shapes in a **coherent way** (WL signal < 1% vs intrinsic alignment ~30%)

Shear signal decomposed into gravitational lensing, intrinsic alignments, and noise:

$$\gamma = \gamma_G + \gamma_{IA} + \epsilon_0$$

Requires statistical measurement over millions of galaxies → **wide galaxy surveys**

Summarising field-level information

2-point Statistics

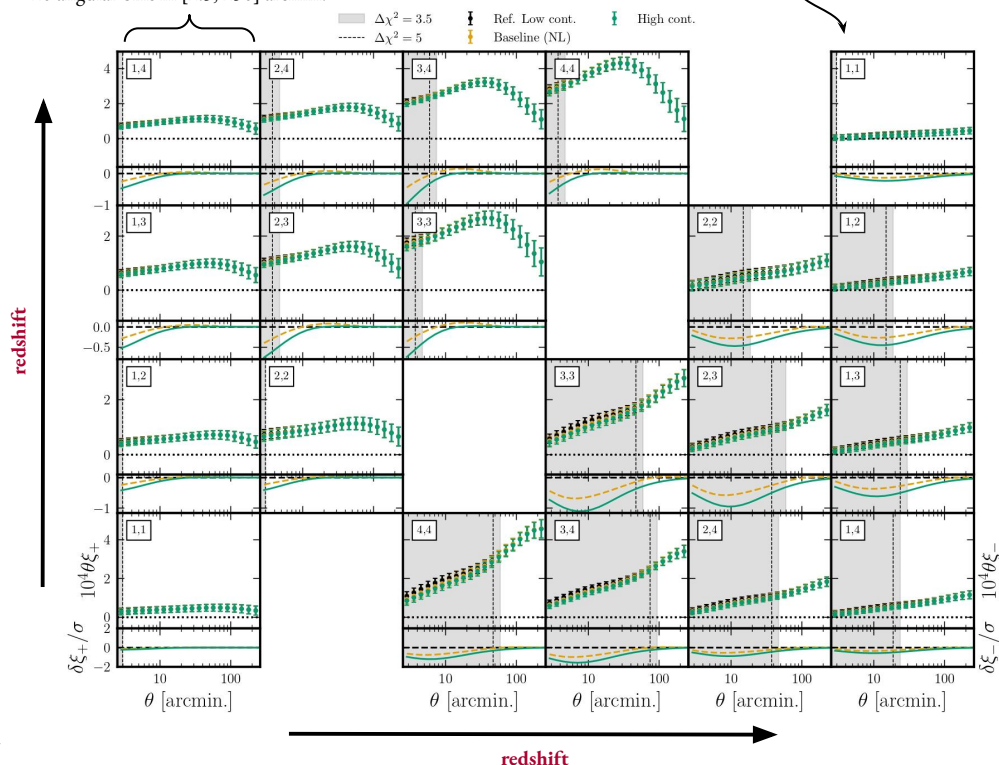

Slicing in redshift bins

Matter distribution is mostly Gaussian \rightarrow encode field information in **2-point correlation functions**

In tomographic redshift bins to learn about the **evolution and growth of structure with time.**

Summarising information from the **matter density** and **shear fields.**

20 angular bins in $[2.5, 250]$ arcmin.

Tomographic 2-point angular correlation function

Stage-IV

Vera C. Rubin Observatory

Euclid

Roman space telescope

cosmic shear

correlation of source galaxy
shapes

$$\xi_{+/-} = \langle e_t(\theta') e_t(\theta' + \theta) \rangle - \langle e_x(\theta') e_x(\theta' + \theta) \rangle$$

$$\propto \sigma_8^2$$

$1 \times 2pt$

galaxy clustering

correlation of lens galaxy
positions

$$w(\theta) = \langle \delta(\theta') \delta(\theta' + \theta) \rangle$$

$$\propto b^2 \sigma_8^2$$

$2 \times 2pt$

galaxy-galaxy lensing

correlation between
position of lenses and the
shape of sources

$$\gamma_t = \langle \delta(\theta') e_t(\theta' + \theta) \rangle$$

$$\propto b \sigma_8^2$$

$3 \times 2pt$ is sensitive to S_8 ,
and is a powerful probe of
dark energy, gravity:

$$S_8 \equiv \sigma_8 (\Omega_m / 0.3)^{1/2}$$

$3 \times 2pt$

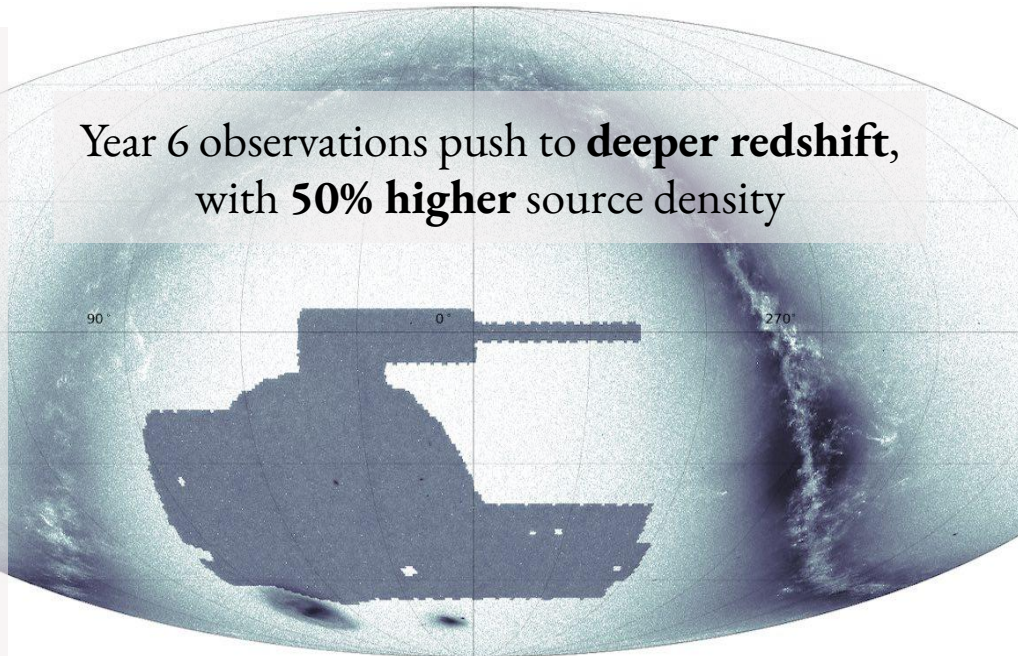

The Dark Energy Survey

A Flagship Photometric Galaxy Survey

- 570 Megapixel camera for the Blanco 4m telescope in Chile.
- Full survey 2013-2019
- **Wide field:** 5000 sq. deg. in 5 bands. $i \sim 24$ magnitude.
- **Growth of structure** and **geometry** probes
- **DES Year 6 results analysing:** positions and shapes of $> 140\text{M}$ galaxies.

Year 6 observations push to **deeper redshift**,
with **50% higher** source density

DES Year 6 3x2pt

The Final Analysis

Huge collaborative effort coordinated by [Martin Crocce](#) and [Matthew Becker](#), with several analysis teams building blocks of the analysis.

Year 6 analysis is built on top of previous DES efforts with major advancements:

- Color dependent PSF modeling, [T. Schutt et al. OJA, 8, 2025](#),
- Modeling on small scales, [DSC, A. Ferte et al. \(in prep.\)](#)
- Photometric redshift uncertainty calibration [[B. Yin et al.](#), [G. Giannini et al.](#), [D'Assignies et al. \(in prep\)](#)], among other improvements.

*> 50 active contributors
spanning many different time zones!*

Source and lens galaxy samples

Source sample = Metadetection [[M. Yamamoto, M. R. Becker et al.](#)]

~ 150 million galaxies

$n_{\text{eff}} = 8 \text{ gals / arcmin}^2$ and $\sigma_e = 0.272$

Reduced shear bias (e.g. in blended objects).

50% more sources than Y3.

Lens sample = MagLim [[A. Porredon, M. Crocce et al.](#)]

11 million galaxies with mag cut : $i < 4 z_{\text{phot}} + 18$

Better star-galaxy cleaning and mitigation of observing conditions,

Redshift estimates with SOMPZ + WZ

Redundancy is relevant!

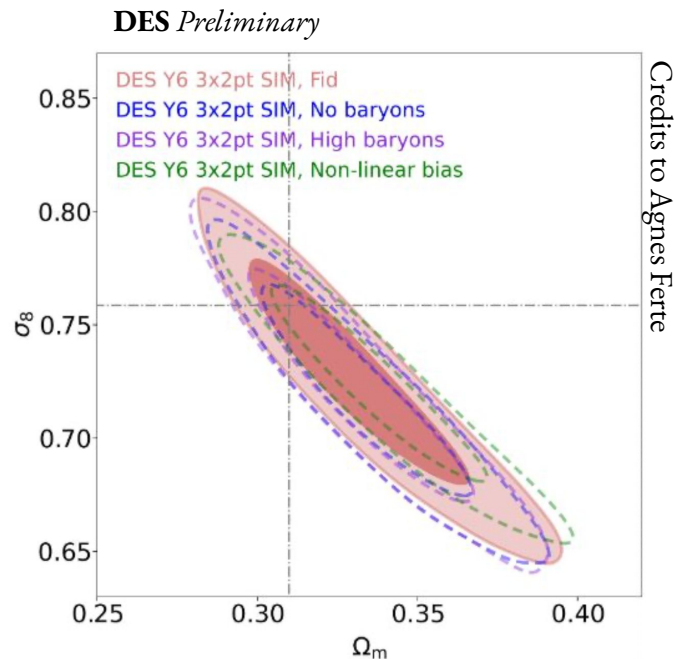

- **Alternative lens sample** = broad \square^2 Redmagic
Twice more galaxies, slightly worse photo- z than Year 3
- **Alternative source sample** = BFD [bayesian fourier domain, Bernstein and Armstrong 2014]
200 million shapes a bit worse shape noise than Metadetect.

Analysis choices for DES Year 6

Pushing to Smaller Scales

Modeling effort lead by [DSC](#), [A. Ferte](#), and [J. Blazek](#), to build the likelihood pipeline, compute the analytical covariance and validate modeling choices ([blinded!](#)):

- HMCode 2020 for **nonlinear DM P(k)**
- **Linear** and **non-linear (EPT)** galaxy bias analyses
- Inclusion of fixed **baryon feedback** signal with $\log(\text{Tagn}) = 7.7$ and flat prior on **neutrino mass**.
- **Intrinsic alignment**
 - TATT 4 parameters for 3x2 and 2x2 (bta=1)
 - NLA and TATT for 1x2
- Mitigate poorly described data points with **scale cuts**: i) linear scales down to 6 Mpc/ h , and ii- non-linear down to 4 Mpc/ h .

Unaccounted baryonic feedback can bias cosmology substantially

Ensuring robust and unbiased cosmology constraints

Scale cuts definition and validation with synthetic data

Scale cuts for the linear galaxy bias analysis efficiently **mitigate unmodeled systematics...**

... keeping potential biases on the best-constrained parameters **below the 0.5σ** threshold.

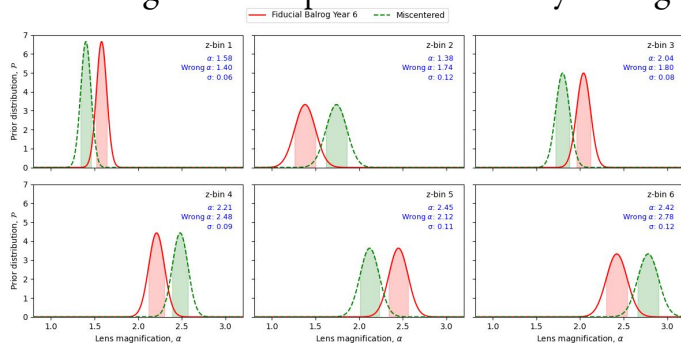

Modeling Calibration Uncertainty

Shedding Light with Simulations

Balrog simulated images ([D. Anbajagane et al.](#)) tailored to DES conditions to derive priors for:

- **Lens Magnification** marginalised with a Gaussian prior centered on Balrog measurements [[E. Legnani et al.](#)]
- **Redshift distributions** marginalised over their shapes using PCA-like modes [[G. Bernstein et al.](#)] and correlating source redshift and shear bias.

Lens magnification priors informed by Balrog

Correlation matrix for source priors

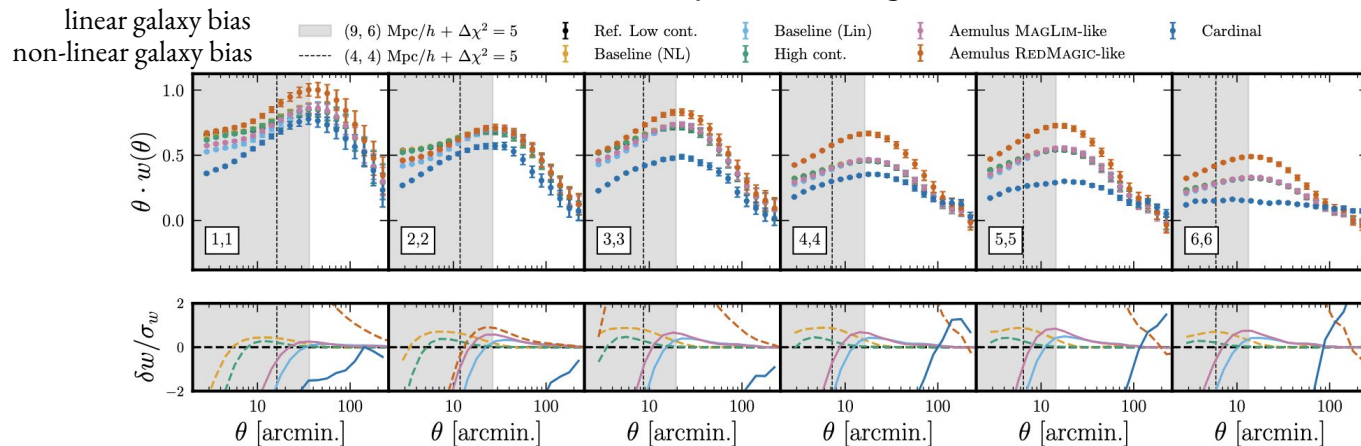

What to expect from DES Year 6?

Mock signal!

Real data signal **passed** all **unblinding** tests! ✓

Galaxy clustering

Measured scales in
[0, 1000] arcmin but
not all are usable!

Analysis	Scale cuts	ξ_+	ξ_-	γ_t	$w(\theta)$	Total	SNR
Cosmic shear NLA	$\Delta\chi^2 = 3.5$	178	89	-	-	267	37.52
Cosmic shear TATT-4	$\Delta\chi^2 = 5$	183	99	-	-	282	39.76
2 x 2pt Λ CDM Linear	(9, 6) Mpc/h	-	-	312	66	378	114.71
3 x 2pt w/Λ CDM Linear	(9, 6) Mpc/h + $\Delta\chi^2 = 5$	183	99	312	66	660	115.85
2 x 2pt Λ CDM Non-linear	(4, 4) Mpc/h	-	-	348	87	435	171.58
3 x 2pt w/Λ CDM Non-linear	(4, 4) Mpc/h + $\Delta\chi^2 = 5$	183	99	348	87	717	172.2
3x2pt LCDM Year linear							87

32% higher SNR

97% higher SNR

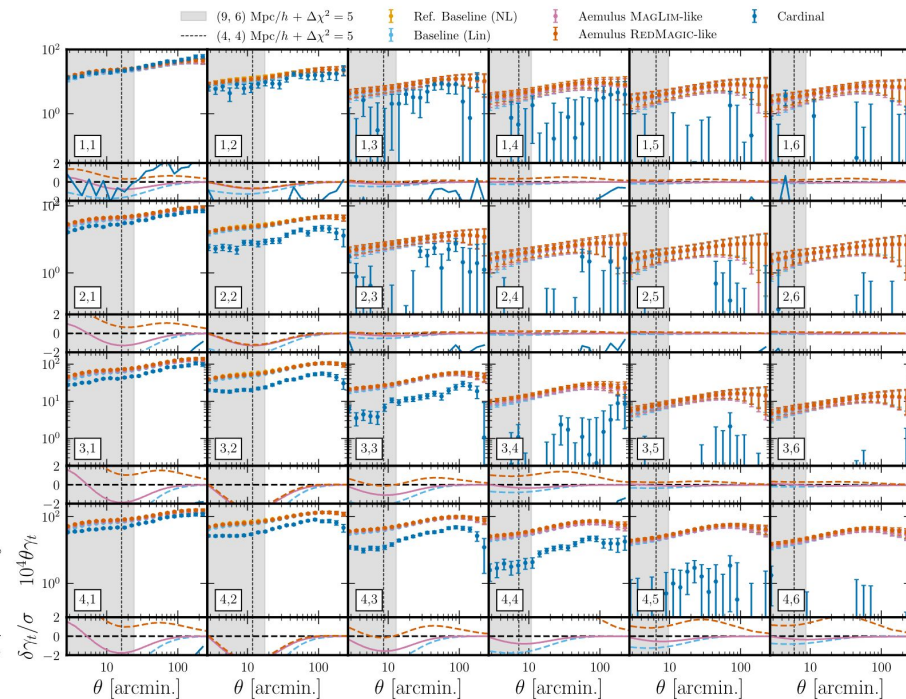

What to expect from DES Year 6?

Total of 50 correlation functions!

Cosmic shear

Galaxy-galaxy lensing

The sustained gain of 1x2pt + 2x2pt

Linear galaxy bias analysis

More than a **factor of 2** increase in FoM in LCDM in 3x2pt wrt shear alone.

3x2pt is very **robust** to systematics in general + **IA and galaxy bias**

$$\text{FoM}_{\Omega_m, \sigma_8} = 1 / \det \left(\text{Cov}_{\Omega_m, \sigma_8}^{-1} \right)$$

Case	$\text{FoM}_{\Omega_m, \sigma_8}$	Relative Difference (%)
DES Y6 - 1 x 2pt	1812.45	-
DES Y6 - 2 x 2pt	2019.41	11.42%
DES Y6 - 3 x 2pt	4942.84	172.72%
DES Y3 - 3x2pt	2068	

What to expect from DES Year 6?

Linear galaxy bias analysis

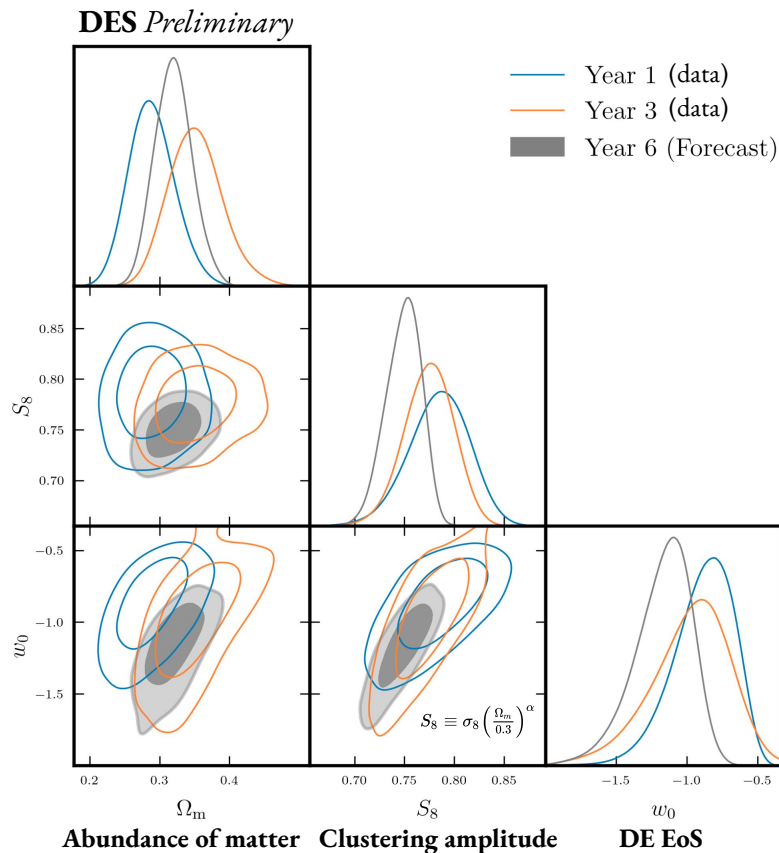

High-dimensional/complex parameter space

with > 50 parameters

Case	FoM $_{\Omega_m, \sigma_8}$	Relative Difference (%)
DES Y3 - 3×2 pt	2011.20	-
DES Y6 - 3×2 pt	4942.84	145.77%

Also, **more than a factor of 2** gain in compared to Year 3 linear (with 4 lens bins and no SR)

Case	$\Delta_\sigma (\Omega_m)$	$\Delta_\sigma (\sigma_8)$	$\Delta_\sigma (S_8)$
Ref.-DES Y3 - 3×2 pt	—	—	—
DES Y6 - 1×2 pt	15.21	-6.14	-19.48
DES Y6 - 2×2 pt	1.78	-8.55	-3.59
DES Y6 - 3×2 pt	-22.39	-27.2	-34.59

DES Year 6 constraints to beyond Λ CDM models

Dynamical dark energy and more

Studies beyond Λ CDM lead by [O. Alves](#), [S. Lee](#), and [M. Raveri](#).

In the light of DESI BAO + SN + CMB w_0w_a , DES can contribute to the discussion with:

- [geometry](#) DES SN + BAO (previous talk,)
- [growth of structure](#)

Adding 3x2pt to DESI BAO + DES SN \rightarrow [~46% gain](#) in $\sigma(w_a)$

+ modified gravity, curvature, massive neutrinos, binned σ_8 , ...

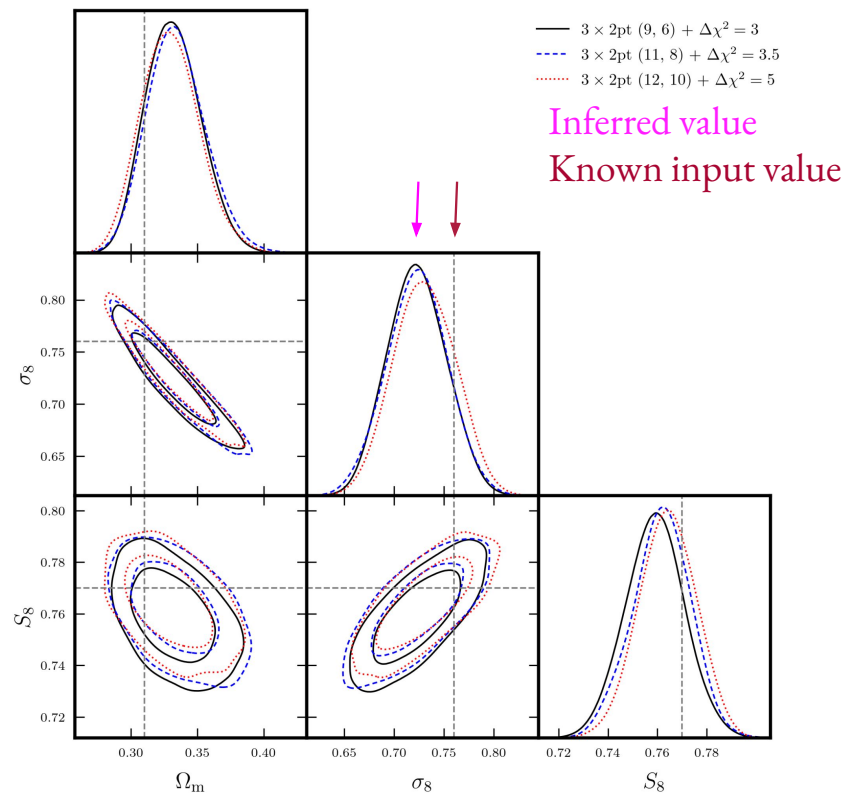

Challenges of a Growing Parameter Space

Projection effects and computational cost

i) High-dimensional parameter space \rightarrow **projection / volume effects** shift inferred values (e.g., neutrino mass, galaxy bias).

ii) Large-scale MCMC campaigns are **computationally expensive** \rightarrow require $P(k)$ emulators and optimized sampling. Other ideas?

1.3M CPU-hours total to get our first version of scale cuts for shear, 2x2pt and 3x2pt Λ /wCDM and in linear and non-linear galaxy bias model (estimate by Agnes Ferte)

Cosmology with DES Year 6 3x2pt

Key Takeaways

- DES sets the benchmark for 3×2 pt cosmology, with forecasted Y6 surpassing Y3 constraining power.
- Analysis improvements: deeper imaging, larger catalogs, improved 2PCF and redshift calibration, refined small-scale modeling.
- Constraints on w / Λ CDM and beyond, informing w_0w_a dark energy models via growth of structure.
- Methodology provides a foundation for Euclid, Roman, and Rubin analyses.
- Tackling theoretical and computational challenges will ensure success for next-generation surveys.
